MACKENZIE VALLEY PIPELINE INQUIRY

Government
Publication

IN THE MATTER OF APPLICATIONS BY EACH OF

- (a) CANADIAN ARCTIC GAS PIPELINE LIMITED FOR A RIGHT-OF-WAY THAT MIGHT BE GRANTED ACROSS CROWN LANDS WITHIN THE YUKON TERRITORY AND THE NORTHWEST TERRITORIES, and
 - (b) FOOTHILLS PIPE LINES LTD. FOR A RIGHT-OF-WAY THAT MIGHT BE GRANTED ACROSS CROWN LANDS WITHIN THE NORTHWEST TERRITORIES
- FOR THE PURPOSE OF A PROPOSED MACKENZIE VALLEY PIPELINE

and

IN THE MATTER OF THE SOCIAL, ENVIRONMENTAL AND ECONOMIC IMPACT REGIONALLY OF THE CONSTRUCTION, OPERATION AND SUBSEQUENT ABANDONMENT OF THE ABOVE PROPOSED PIPELINE

(Before the Honourable Mr. Justice Berger, Commissioner)

Inuvik, N.W.T.

January 29, 1976

PROCEEDINGS AT INQUIRY

Volume 120

APPEARANCES:

Mr. Ian G. Scott, Q.C.,
Mr. Stephen T. Goudge,
Mr. Alick Ryder and
Mr. Ian Roland for Mackenzie Valley Pipeline
Inquiry;

Mr. Pierre Genest, Q.C.,
Mr. Jack Marshall, and
Mr. Darryl Carter for Canadian Arctic Gas
Pipeline Limited;
Mr. Reginald Gibbs, Q.C.,
Mr. Alan Hollingworth &
Mr. John W. Lutes, for Foothills Pipe Lines Ltd.;

Mr. Russell Anthony &
Pro. Alastair Lucas for Canadian Arctic Resources
Mr. Garth Evans Committee;

Mr. Glen W. Bell and
Mr. Gerry Sutton, for Northwest Territories
Indian Brotherhood, and
Metis Association of the
Northwest Territories;

Mr. John Bayly
or
Miss Leslie Lane for Inuit Tapirisat of Canada,
and The Committee for
Original Peoples Entitle-
ment;

Mr. Ron Veale and
Mr. Allen Lueck for The Council for the Yukon
Indians;

Mr. Carson H. Templeton, for Environment Protection
Board;

Mr. David Reesor for Northwest Territories
Association of Municipal-
ities;

Mr. Murray Sigler for Northwest Territories
Chamber of Commerce.

Mr. John Ballem, Q.C., for Producer Companys;

3 (PROCEEDINGS RESUMED PURSUANT TO ADJOURNMENT)

4 MR. BAYLY: Before we begin
5 the cross-examination of Dr. Pimlott, I'd like to
6 express a concern that the Committee for the Original
7 Peoples Entitlement has with regard to the scheduling
8 of hearings of the Arctic Waters Oil & Gas Advisory
9 Committee, and I don't want to go into the things that
10 this Committee is to consider because I understand the
11 problems of their terms of reference being different
12 from your own, sir. I'm only interested for the purpose
13 of this expression of concern to inform you that, for
14 various reasons, we feel that the scheduling may affect
15 the participation in your Inquiry, and in particular at
16 the community hearings which have been scheduled for
17 February and March.

18 Now, we first heard of the
19 schedule of these hearings in detail in the middle of
20 January and when we had heard this, a telex was sent
21 to the Minister on January 14, 1975 and going to the
22 particular area of concern to this Inquiry, we said
23 in this telex:

24 "We wonder why your Department at this time is
25 sending groups such as the Regional Planning
26 Committee and the Arctic Waters Oil & Gas
27 Advisory Committee into communities to discuss
28 issues Berger will be pursuing in another few
29 weeks. We trust it is not an attempt to confuse
30 people and usurp the authority, or jeopardize

1 the success of the Berger Inquiry."

2 And later in the telex,

3 "Any attempt to subvert the process of the
4 Berger Inquiry must be protested in the
5 strongest terms."

6 Now, we failed to receive a
7 reply to that by the 20th of January, and sent a
8 telegram to the Minister, asking for a reply, and a
9 reply was sent signed by the Minister dated January
10 23, 1976, in which there was no reference to the con-
11 flict between the scheduling of the hearings and
12 the scheduling of the Berger Inquiry with the exception
13 of the last paragraph, in which it says:

14 "It is perhaps regrettable that all these
15 matters have come before us at the same
16 time, but there would be no advantage to
17 delaying the community meetings which I
18 regard as an important component of the
19 decision-making process."

20 In reply to that, Sam Raddi
21 sent a telex to the Minister again in which the
22 following statements were made:

23 "We are asking that the community consultations
24 by the Arctic Waters Oil & Gas Advisory Commit-
25 tee be meaningful, not token; to help make it
26 meaningful we are asking that you postpone
27 the tour until after the delta phase of the
28 Berger Inquiry, which will be about three weeks.
29 We are not asking that the Arctic Waters Oil &
30 Gas Advisory Committee not hear the communities

1 as part of their decision-making process."

2 And later in the telex on the same subject,

3 "I am concerned that the great rush to have
4 meetings by the regional plan, Palliser
5 information tour, the Arctic Waters Oil &
6 Gas Advisory Committee and the Berger hear-
7 ings will render community meetings useless.
8 People are prepared for Berger."

9 And later in the telex,

10 "There was never any consultation with the
11 communities or us as to when would be the
12 best time to have the hearings."

13 Now, in reply to that we
14 received, signed by the Secretary of the Arctic Waters
15 Oil & Gas Advisory Committee in Yellowknife an
16 itinerary with the hearings set out as follows:

17 On the 3rd of February,
18 Holman Island and Sachs Harbour.

19 On the 4th of February,
20 Paulatuk and Tuktoyaktuk.

21 On the 5th of February,
22 Aklavik.

23 On the 6th of February,
24 Inuvik.

25 No mention again of the concern
26 that was expressed.

27 A telex was also received
28 dated January 28, 1976 from the Deputy Minister in
29 which no mention was made of this concern, and sir,
30 we raise this with you because we feel that it maybe

D. Pimlott
Cross-Exam by Goudge

1 a matter that you wish to consider in the light that
2 it may affect the success of the community hearings
3 which you have scheduled in the delta communities.
4 We wish to state that we view with grave concern any
5 action, whether accidental or conscious, to jeopardize
6 the success of your Inquiry.

7 We did learn by way of
8 parallel example that when the Science Council last
9 spring informed the Department of Indian Affairs of
10 its intention to hold hearings in Inuvik, at that time
11 the hearings were re-scheduled because of the concern
12 that the Department felt that it might jeopardize your
13 Inquiry. We have brought these concerns up with regard
14 to their own hearings, and we have not even had an
15 acknowledgment. I realize your position in this, sir,
16 and that you're not in charge of what the Arctic
17 Waters Oil & Gas Advisory Committee does, but there
18 may be a point that goes to the success of your
19 own Inquiry, which is a concern to you.

20 THE COMMISSIONER: Well, thank
21 you, Mr. Bayly. Any questions of Dr. Pimlott?

22 MR. LUTES: I have no questions.

23 MR. CARTER: No, I have no
24 questions.

25
26 DOUGLAS PIMLOTT, resumed
27 CROSS-EXAMINATION BY MR. GOUDGE:

28 Q Let me begin with you
29 by seeing if I understand your evidence as it relates
30 to the environmental programs you say ought, in an

1 optimum sense, to go on before any offshore drilling
2 is undertaken in substantial quantity.

3 To take you back to the
4 beginning, I understood you to say that you would have
5 preferred the Beaufort Sea program to have been a 3-
6 year program rather than a one year or two year program,
7 that you thought three years were required for the
8 assessment that that program was intended to carry out.
9 Is that correct?

10 A Yes. I use three years,
11 I stated that three years was the minumum that I
12 considered was required. In the time that I worked
13 with the science council I was forced to think a
14 great deal about times for ecological studies, because
15 there's a great inclination for natural scientists,
16 I guess particularly on the ecological side, to talk
17 about, oh we need ten or fifteen years, and quite
18 frequently I guess other processes and other options
19 in society are, in the offing must be considered at the
20 same time.

21 And so when I talk about this
22 personally, I tend to be, to go down to what I think
23 are minimums, and in talking about a minimum three
24 year period, I was just reflecting on a little
25 that I've learned about the Beaufort Sea, in the time
26 I'd worked in the western arctic; and I had known that
27 very often in a ten-year cycle of the sea, seldom--
28 that you may seldom have two years that are quite
29 comparable. And faced with a situation like that, it
30 seemed incongruous to me to talk about a one year

1 program; and yet there was something which was pressing,
2 and which preliminary commitments had been given.
3 In that kind of a context I talked about a three year
4 program being a minimum. I guess it was in a hope
5 that the law of averages would sometimes work out
6 favorably, so that a reasonable average for sort of
7 that ten year cycle, might be struck, during a three
8 year study.

9 Q So you begin with that
10 view, and then you say that, as I understand you, that
11 that program, as it was carried out, should become
12 part of a two phase program that you referred to,
13 which I understand to have as one part basic environmental
14 research, and as a second part environmental impact
15 research. Do I understand you correctly as to that?

16 A That's correct.

17 Q And you then conclude
18 your evidence by saying that there is a ten year gap
19 between development that is proposed and technology
20 capacity. Is that a fair summary of your ten year
21 gap statement?

22 A Yes, and I think that's
23 fair. The industries themselves, I would point out,
24 have been talking in very comparable terms, and this
25 is part of this dilemma. I had learned a lot more in
26 the interim about complexities and for instance, I have
27 before me a paper that was presented in 1973 at that
28 congress that I referred to, the offshore congress, in
29 Paris, when they considered offshore drilling; and in
30 it it has a table which suggests that from the time

1 that you start a research program on the environmental
2 area, until the time that you can begin the first
3 exploratory drilling, is a minimum of 7½ years should
4 be involved; and in talking about an absolute minimum
5 in terms of the pressing reality, and in terms of
6 something that would really be desirable in society,
7 and considering the day to day problems that were
8 faced by the Beaufort Sea Commission, I had to say, I
9 felt that in fact, if we were really talking in terms
10 of an optimum situation, it would in fact, from the
11 time that you started this work, it would be pretty
12 close to a 10 year period.

13 Q Yes sir. The work though
14 as I understand it, you see as having to proceed along
15 3 research fronts. A basic environmental research
16 front, an environmental impact research front, and a
17 technology research front. Those are the 3 fronts that
18 have to be moved against. Is that correct?

19 A What did you list as the
20 second one?

21 Q Environmental impact.

22 A Where are you drawing that
23 specifically from my evidence?

24 Q Well let me ask you to
25 turn to the top of page 25, where there you refer to a
26 two phase research program; the first phase being a
27 carefully developed long term program of basic research,
28 and the second, which I read, perhaps inaccurately, to
29 refer to an environmental impact research program, or
30 phase.

1 A In my testimony when I
2 reworked it for presentation, I stated it this way. In
3 my view such research should have two phases: one, a
4 carefully developed long term program, and then at the
5 end of Beaufort Sea environment, I placed two. There
6 is also a need for a more specialized environmental
7 impact research program, and the highest priority would
8 be research which is designed to identify or predict
9 potential problems, which could result from the various
10 aspects of petroleum development.

11 Now in that impact discussion,
12 I included the idea that the monitoring would be
13 included as part of that. I have a rather strong
14 conviction that it's very important that we learn from
15 projects which are ongoing, both for the benefit of
16 that area and for the benefit of other areas which may
17 be developed in the future.

18 So I in fact had identified
19 two, but I had included environmental impact research
20 program as including a major monitoring program as well,
21 so possibly it might be reworded to say there was three.

22 Q Yes, without breaking off
23 the monitoring from ~~your~~ environmental impact research
24 front, I refer to a third necessity as being research
25 to overcome the technological hurdles that you say are
26 presented to the industry. That is, you've told us
27 that in your view there is a ten year gap between what
28 they want to do, and their know-how.

29 A If you cared to ^{classify} / it that
30 way, I would be quite satisfied to say the technological

1 one is the third.

2 Q Yes. And you'd admit
3 of course that there has be work progressing on all
4 three fronts, the basic research front, the impact
5 front, and the technology front.

6 A That's correct.

7 Q Your concern, I take it,
8 as to where we are at the moment, is that there is not
9 enough done on each of those three fronts?

10 A One of my concerns in the
11 technological area has to do with the fact that even
12 some of the systems which appear to be on the horizon,
13 are no being put even to the prototype stage. In
14 publications, for instance, one of the background
15 publications that deals with this; there's one in the
16 Petroleum Engineer of January 1975, and it's by Dr.
17 Gordon Jones, president of Global Marine Arctic Ltd.
18 of Calgary. The article is titled, "Arctic Poses
19 Extreme Technical Challenges", and then he talks about
20 the various possible systems. One of the ones portrayed
21 is a self-contained arctic cushion air drilling system,
22 and he infers that this system essentially could be
23 developed, or could be taken to the prototype stage.

24 But there would be a couple of
25 years construction time even there, and so this concern
26 is that we don't go to the experimental stage. We
27 talk about all the development we're going through, but
28 we won't actually go to the experimental stage of
29 testing the prototypes.

30 I was getting into the same

1 type of thing a bit yesterday with the monopod. It has
2 approval in principle. It would be a number of years
3 in a testing phase to determine its value; so the
4 concern there, and the reference to time, is a complex
5 one which deals both with research and with the fact
6 that we don't want to seem to want to get on to
7 developing prototypes, so that we could really get into
8 the applied part of the research.

9 Q Yes. You've no doubt
10 though sir, that there has been, up until today, research
11 and experimentation to some degree on all three fronts,
12 that we identified: the basic research front, the
13 impact front, and the technological front. No doubt in
14 your mind that we've gone some distance down those
15 three roads, but not far enough. Is that your position?

16 A Yes, that's my position.
17 I think we just haven't gone nearly far enough in the
18 third phase, that you've listed as "3".

19 Q Well, now you're
20 anticipating my next question. I'd like to ask you to
21 compare, if you will, our present position on each of
22 those three roads. Are we least adequately prepared
23 on the technological front, or the environmental impact
24 front, or the basic research front?

25 A Well, I suppose I would
26 be glad to jump out in the middle of the lake and
27 attempt to deal with that question. I would like to
28 call attention to the fact that I refer to my work as
29 investigative journalism, and perhaps too, an
30 application of political science techniques, and I

1 admit to not being a technical expert, in terms of
2 offshore drilling. In fact, I consider it an incongruous
3 situation, that this type of question of necessity is
4 addressed to an ecologist, so that some information
5 can come before the Commission. I admit to a very
6 great sense of humility about my capabilities of
7 dealing with that question.

8 Now, if we talk about offshore
9 drilling systems, the ones that are far in deep water
10 areas, there was a two year period required for the
11 construction of the drill ship system, and that happened,
12 that two years was required, when the the actual hulls
13 were already constructed. These were war-time hulls
14 that were in mothballs, that were purchased by Dome
15 petroleum, and adapted to drill ships, and that required
16 a two year period.

17 Now there's nothing significant
18 about that technological development at all. It is a
19 traditional approach to the use of drill ships. It's
20 not dynamic positioning, and the one thing that they
21 did was to ice strengthen it. So as I said yesterday,
22 sir, it could deal/with the Beaufort Sea in summer. So
23 just to go to a very traditional system, there is two
24 years required.

25 I referred yesterday to the
26 statement by the official of Shell Oil, again at that
27 international congress in 1973, which said that when
28 they came to look at this, that none of the background
29 information associated with design, that was needed for
30 design, was available to them. And so, I interpret

1 that s meaning that considerable lead time is
2 necessary to go into a system that is really capable of
3 drilling at any period of the year, beyond the open
4 window, and the oil companies tend to refer to the
5 periods that they can work as the open windows. And
6 the open window in the Beaufort Sea is about four
7 months.

8 So I would argue that a system
9 that is only capable of dealing with that open window,
10 and when that open window may not exist every year as
11 in fact it didn't in 1974, then we're almost at square
12 one in terms of working on a technological system, that
13 is capable of dealing with a marine environment. So
14 in the deep water areas I say, it's obvious that there's
15 a lot of time involved. Whether the ten years is a
16 critical - I didn't have a design. I was going partly
17 on this type of paper to gain understanding, but it
18 seemed under those circumstances to ^{really} deal with the
19 Beaufort Sea beyond that 190 to 120 day window that 10
20 years was a pretty realistic time and we're not very
21 far down the road, and I think in that respect, that
22 is probably the lowest level in terms of our progress.

23 Q If I asked you to rank
24 our shortfalls on the three fronts on a scale of one
25 to ten, as we say --

26 A Well I'd say that in the
27 case of dealing with the offshore -

28 Q Dealing with the offshore
29 you would rank technology lowest on that scale.

30 A Yes, I think I would be

1 inclined to rank it pretty close to square one, perhaps
2 square two, because at least we've been talking to them,
3 at least we have papers like this now, that are
4 attempting to talk about them. But certainly not very
5 much beyond that.

6 Q And using the same scale,
7 I take it you feel that the present state of
8 environmental impact research is not quite so inadequate,
9 and perhaps would rank higher on the scale.

10 A I think it is somewhat
11 higher, yes, because in some of the areas, for instance,
12 in the interest of the native people, we've had fairly
13 good research programs going; apart from this, on seals.
14 At the arctic biological station there have been a
15 continuing program, an international program, on polar
16 bears. The Canadian Wildlife Service as part of their
17 research have had some research going on a number of
18 the, particularly snow geese, and some of these forms.
19 The Canadian Wildlife Service had a fairly good study
20 of the murre. This doesn't apply much to the western
21 Arctic, but that was done in the fifties and sixties.

22 So I think probably in the
23 cases of - but the areas of great shortcoming, on say
24 in this same area I'll talk about, these are the ones
25 where there was possible - but the areas of really
26 great shortcoming in ecological areas as I see it are
27 in the areas in the lower levels of the food chains.
28 I think the reports from the Beaufort Sea study that
29 deal with phyto and zoo plankton, and their distribution
30 and not only their distribution, but even the species and

1 their inter-relationships; none of these things, this
2 is a very gross area of ^{our} lack of knowledge.

3 Q Yes. You're now speaking
4 though of research in what I've defined in the basic
5 research, rather than the environmental/^{impact} research.

6 A Yes.
7 Q If I'm right sir, before you get to that could you
8 put the present position of environmental impact
9 research on our scale of one to ten, having acknowledged
10 that we're not quite so deficient in that area as we
11 are in the area of technological research?

12 A Well I don't see - if
13 we had basic research that was adequate, environmental
14 impacts research would start there, we wouldn't do any
15 so-called base line research at all. We wouldn't have
16 to. We would just use information that existed. So
17 it's very difficult to come to terms with your question
18 when in fact we have very large inadequacies in the
19 basic area, because it's on the basic area that impact
20 assessment must be based. I find it very difficult to
21 separate those two.

22 Q Okay, I understand that.
23 Let's then go to the basic research front and let me
24 ask you the same question in connection with it.
25 Where do you put our present position in basic research
26 on a scale of one to ten? I take it from your earlier
27 answer that you feel there are fewer inadequacies with
28 that than there are with our technological research
29 position.

30 A I think you'd have to
break it down into a few subsections. Some of those

1 obvious important species that have had continuing
2 research programs—polar bears, seals, some of the
3 snow geese, some of the sea birds—in that area I think
4 that we're up around square four or so, perhaps even
5 a little higher, I'm not sure, but we're there. In
6 the case of fish, for instance, we're awfully close to
7 square one. For instance, Tuktoyaktuk has been
8 dependant on an interesting harbour fish, they do a
9 lot of netting in the harbour. When I was here with
10 COPE I tried to find out what we knew about the base
11 of the Tuk fish resource, and I dropped into Yellowknife
12 at the Fishery Service Office and I found that basically
13 there was virtually no background information on the
14 Tuk fishery. The preliminary reports for the
15 Beaufort Sea project are just beginning to identify
16 the coastal areas as being of key importance. As I
17 mention^{ed} yesterday, the lagoons and bays and things as
18 being very important to nurseries. So in that aspect
19 of our knowledge, we're very close to square one or
20 two.

21 In dealing then when you get
22 down to the basic elements of the food chain, the
23 phyto and zoea plankton and so on, the reports by
24 Dr. Granger and Dr. Percy and some of their associates
25 at Arctic Biological Station, I think, will show
26 clearly that that is a square one situation.

27 So it ranges from I would say,
28 in that area, from roughly a one to four, one to five,
29 in the best study situation .

30 Q But overall, your position

1 is that our inadequacies there are less stark, than
2 our inadequacies on the technological research front?

3 A Yes. And one of the
4 things I'm counting on in that is the fact that we can
5 make up some of these. In the case of the technological
6 side, you can't start until your technology has been
7 developed and your system has been constructed. But in
8 the case of basic research, you can pick up some of
9 the inadequacies as you go along, and that's a very
10 important consideration.

11 Q Now sir, having asked
12 you to compare where we're at in these three research
13 fronts, you're an Arctic ecologist who has obviously
14 given a good deal of thought to those research fronts,
15 I'd like to ask you if you would to go through each of
16 the three fronts with me, and give me your opinions,
17 if you have any, as to the nature in a little more
18 detail of the study programs you see as necessary
19 bring us from the square we're at to the square you
20 think we should be at. Let me begin with the basic
21 research front, and ask you if you can define for me
22 the scope of the research program that needs to be
23 done, in your view.

24 A Are you asking me here
25 to deal only with the biological side of this
26 equation, because I really simply cannot deal with
27 the physical side. That's the realm -

28 Q By all means. Limit
29 yourself then to the biological side.

30 A Well then I would remind

1 you also that I admit again, you referred to me as an
2 Arctic ecologist. I have worked in the Arctic on large
3 mammals, I have attempted to gain understanding. A
4 great deal of my understanding in the case of the
5 science Council study came through the eyes of
6 associates. In a job like that, as in many elements
7 of the Commission hearing, your skills have to be as
8 a brain-picker. You have to be able to gain
9 understanding from other people, and with that
10 recognition, I guess I would be glad to attempt
11 something.

12 I think in dealing with this
13 biological area, we're always attempting to find out
14 what our key limiting factor is in a system. Sometimes
15 there's no simple ones, sometimes there can be sort of
16 like key logs in a log jam ^{and} could be very very
17 critical. And so, in gaining an understanding of the
18 interactions of a system, it's a real effort to try
19 and understand what kind of limiting factors you might
20 be involved with.

21 If I might digress slightly
22 to provide an example of one of those. When they were
23 doing the polar bear work in the Hudson Bay area, they
24 found that there was a very important polar bear
25 denning area, in which they wanted to do winter
26 exploration, and it had the potential for great
27 problems. Bears going into sites and I suppose
28 coming out after the young were born, and so on. In
29 that situation, they were able, just by simply having
30 a detailed understanding of the importance of an area,

1 just to avoid it at a critical time, and so avoid the
2 problem.

3 So in looking at any of these
4 situations, you're trying to get that kind of
5 understanding, so that through the use of this
6 understanding you can mitigate, or prevent things from
7 occurring. So, in looking at this whole thing from the
8 point of view of limiting factors, you need to
9 understand whether there are important things that
10 could be lost.

11 In my own field, for instance,
12 I've studied wolves for many years - or on Baffin
13 Island, the presence of caribou is absolutely vital.
14 You can't have wolves on Baffin Island unless the
15 caribou herds are maintained.

16 I think it's possible that in
17 the marine environment, that there may be key factors
18 involved that might be vital, for instance, to seal
19 production, and I don't think that we understand the
20 intricacies of the inter-relationships within the
21 community, or the details of the workings of the
22 community, and the different stages of food chains.
23 We can't really pin any of those things down.

24 So this is where I see the
25 problems involved. You can identify nursery areas and
26 feeding areas fairly quickly, but to identify real
27 problems like that, that's where where you get into the
28 critical time factor.

29 And so I would say, to sum
30 up and answer your question as directly as I can, I

1 think it's in this whole area of trying to sort out
2 community inter-relationships and food chain
3 relationships, that are very important to a reasonable
4 understanding of the workings of the Beaufort Sea
5 eco-system, and it's in trying to unravel those things
6 that a lot of time is likely to be involved.

7 THE COMMISSIONER: Hasn't
8 the experience in the north been, Dr. Pimlott, speaking
9 generally, that the research on the nature of
10 eco-systems is not usually carried out until a resource
11 is discovered and it becomes apparent that something
12 has to be learned about the eco-system before
13 exploration, whether it be for oil and gas, or for
14 lead or zinc, or for some other resource, occurs?

15 A This has been very much
16 the case. In the paper I referred to yesterday by
17 Dr. John Sprague, I didn't refer to it directly, but
18 the follow-up that I referred to yesterday was a paper
19 by Dr. John Sprague, prepared for the Canadian Arctic
20 Resources Committee workshop in 1972. The purpose of
21 that workshop was ^{to try} to see where we stood with respect
22 to things like this. He pointed out that at that time
23 the principal work on the Arctic marine environment was
24 constituted, was being done by nine people and those
25 people also had the responsibility for marine mammals
26 on the east and west coasts, as well as in the Arctic.

27 I think that this reflected,
28 in part, a fundamental bias that then existed in the
29 Department of Fisheries, which then became part of the
30 Department of the Environment, because the pressures

1 on the Department had always been to serve the interests
2 of the fisheries on the east and west coasts, it was
3 reasonable enough; and so the Arctic section of their
4 work always lived a very starved existence, and I think
5 that it perhaps was inevitable in our society, I
6 suppose, that this is what happens, but it certainly
7 was the case.

8 MR. GOUDGE: Dr. Pimlott, in
9 describing in general terms at least, the outline of
10 the program you see as necessary, on the basic research
11 side, you deal with inter-relationships, and I take it
12 that the problems that you describe cut across species,
13 they apply to a variety of species and the
14 inter-relationships between them.

15 A Yes, that's correct. An
16 attempt is being made, for instance, to get over some
17 of these problems. In our application of science, we've
18 been very inclined to work as single scientists, we're
19 not very anxious to get together and work with somebody
20 else. That type of thing is being broken down by the
21 Beaufort Sea project approach, and that's one of the
22 reasons why I said yesterday that I think we have to
23 more or less force scientists to come together and work
24 in a common framework.

25 There's been some work on this
26 before, for instance, there's been very close
27 relationships, I believe, between the people who studied
28 polar bears with the Canadian Wildlife Service, and the
29 people who studied seals, from the Arctic Biological
30 Station. So there have been cases where it has been

1 gradually coming about, but it's something which
2 scientists need to be clobbered on a little harder to
3 get that kind of group working relationships going.

4 Q Well, given that the
5 program you describe is of the nature you describe,
6 and inter-disciplinary, if I can use that phrase, in
7 your view whose responsibility would it be to carry it
8 out? Industry's, or government, or shared, or what?

9 A I've thought a lot about
10 that, in the course of trying to do a chapter on
11 research in the book which I referred to yesterday,
12 "Oil Under The Ice", and it seems to me that when you
13 check all along the line, that industry performance is
14 basically better than government's, and I think that in
15 view of this kind of lack that I just referred to, in
16 the past, in terms of developing background basic
17 research programs, I really feel that there should be
18 special allocation on the government's side, for the
19 basic research. I feel that the monitoring and the
20 impact assessment should be funded by industry. I'm
21 not satisfied to have that kind of research done under
22 an APOA type of arrangement, it just simply doesn't
23 work out, for you get studies being commissioned by
24 two consultants under proprietary arrangements, where
25 the information can be held secret for five years, and
26 which terms of reference can be given which are not
27 broad enough.

28 So I believe, to answer your
29 question directly, that the basic area should be the
30 responsibility of the government; that there should be

1 a catch-up program in the Arctic, and the monitoring
2 and environmental impact research should be basically
3 funded by government with some kind of an organization
4 which is responsible for deciding what needs to be done,
5 and for allocating the contracts.

6 Q Did you mean to say the
7 environmental impact studies should be funded by
8 government, or by industry?

9 A By industry.

10 Q Well let me come to the
11 environmental impact side in a moment, but to complete
12 the basic research side, have you given any thought at
13 all to the cost of the program that you advocate?

14 A No, I haven't. I'm
15 aware of the fact that Immerk cost 9 million dollars to
16 drill, and the drill ships systems, ^{I think,} are costing 130
17 million, and so -

18 Q It sounds like you're
19 leading up to a large number.

20 A No, I'm not going to
21 state the number, I'm just going to say that I can't
22 see, under any reasonable system, that the money that's
23 necessary for research should in any way limit,
24 considering the scale of the expenditures, that are
25 necessary.

26 Q Do you have any ballpark
27 that you can place it in? That is, are we talking
28 about a million dollar program, or a 50 million dollar
29 program, or what?

30 A Well, the Beaufort Sea

1 research program was originally funded for about 5
2 million, and according to Dr. Millen, it has cost, if you
3 put all the things together into a real cost, it's
4 come up to about 12 million. And so I think that in
5 view of say a ten-year research program that dealt
6 with physical and biological environments, something
7 in the order of the expenditures that are being
8 allocated for the western part of the Beaufort Sea,
9 something of the order of 40 to 50 million dollars
10 would probably be required.

11 You have the very high costs
12 of providing ship services, and so on, and it does
13 come, it's expensive research. You need aircraft, you
14 need ship services, and I think 40 to 50 million dollars
15 is ^{certainly} somewhere in the ballpark.

16 Q And this is for the basic
17 research program that you speak?

18 A No, I was thinking in
19 terms, at this time, that this would be the combined -

20 Q Basic research and
21 environmental impact research?

22 A Yes, 40 to 50 million,
23 within that.

24 Q Well, let me move in a
25 little more detail then to what I've described as the
26 second front, that's the environmental impact research
27 front. You, I take it, link that closely to the basic
28 research front?

29 A Yes, because I say that,
30 as I said, what you do in environmental impact research

1 depends a very great deal on what your background --
2 on the background knowledge available to you. A very
3 large part of the Beaufort Sea research wouldn't have
4 had to be done if the government had had an accurate
5 research program in the north, because we would have
6 known a lot of the things about - we'd^{have}/known where the
7 Tuk fish come from and what are their important nursery
8 areas and so on.

9 Q Well on that side of the
10 research picture, at the moment, have you given any
11 thought to the nature of the program that you advocate
12 as necessary, to get us where we should be?

13 A No, I've thought only in
14 terms of some principles. For instance I had the
15 opportunity to examine some of the environmental impact
16 assessments that have been made, and I think that they
17 have been made under very restrictive terms of reference,
18 and very restrictive budgets.

19 For example, I studied in some
20 detail the impact assessment that Pan-Arctic submitted
21 for offshore Hecla, and I was absolutely appalled by it.
22 I think I said at the time, and I think it was a
23 realistic statement, that I could have given, expected
24 a fourth year ecology student working with me to have
25 done a comparable job, for a one-course credit, perhaps
26 even for one semester. It was a library research,
27 it was so filled with vague generalities and inanities,
28 that it was incredible. And then I saw others that
29 were supposed to be improvements, and they were very
30 poor. So the principles that I have been thinking about

1 have been that somehow, the environmental impact
2 assessment must have a moderating body of some kind,
3 that decides what kind of impact assessment needs to
4 be done, how much money will be expended on it, and
5 what the terms of reference will be. It just cannot
6 continue as a realistic process, if industry is able
7 to establish the terms of reference and the limits of
8 funding for the projects.

9 Q Well to I understand you
10 to imply that that moderating body, by which I take it
11 you mean a body directing the environmental impact
12 research, is that body in your view required to be a
13 government body?

14 A Yes, I have long
15 maintained that there should be a strong separation in
16 government between the agencies of government which
17 regulates the things pertaining to the environment, and
18 that which promotes the development, and I think that
19 this function could well be performed by some kind of
20 a body either constituted by or ^{as} part of Environment
21 Canada. It is not logical for it to be a body in a
22 department which has the ~~role~~ of promoting the development
23 of the resources.

24 Q You begin with the
25 proposition, as I understand you though, that it should
26 be some government body as opposed to a non-industry
27 private body.

28 A Yes, I have a strong
29 respect, I think, for the system, the government system,
30 the democratic system in which we work, and I think that

1 our politicians should ultimately be responsible for
2 things that pertain to the protection of our environment.
3 We should be able to call them to task. And so I tend
4 to think that that's where the responsibility should
5 lie.

6 Q Yes sir. Now that's
7 principle number one. Any others?

8 A Well I guess the second
9 principle relates to what I said before, is the work
10 associated with environmental impact assessment should
11 look strongly both to the present and to the future.
12 It should help us to do as much as possible to prevent
13 problems with current development, and to mitigate
14 those which may occur.

15 It should give us the insight
16 and the understanding so that we can do a lot better
17 when we're working on ones a little way down the line.

18 Q Yes. And without
19 fleshing out the particulars of the study, or the
20 studies you see necessary, to get us where we should be
21 on the environmental impact front now, those two are
22 the main principles that you would advocate as the
23 foundation for the research.

24 A I think so. I'm not very
25 good at instantaneous thinking out of these things. I
26 tend to be a strong bull session man, who starts to
27 develop ideas and then starts testing them on people.
28 So if you ask me again a week from tomorrow, after
29 you've stirred my thinking up to be more specific on it,
30 I probably would throw a few more curves, but I don't

1 have many instant answers at the moment.

2 MR. BAYLY: We will probably
3 be bringing Dr. Pimlott back so he can answer that
4 question.

5 A Don't threaten me now,
6 Mr. Bayly.

7 THE COMMISSIONER: Maybe you
8 should bring forth your ecology students.

9 MR. GOUGE: That's right.

10 Well sir, let me ask you then,
11 moving to the third area of research, and perhaps you
12 feel reluctant to answer any questions on it, and say
13 so if you do, but have you given any thought to the
14 general scope of, and perhaps even the particular
15 parts that would make up the technological research
16 program that you feel has to go on over the next decade
17 or something less.

18 A The really big bind, as
19 I see it, in the technological research, has to do with
20 drilling in moving ice. There isn't anything - it
21 seems to me that there isn't any really big problems
22 associated with getting a drilling system that can work
23 in winter in the Sverdrup Basin.

24 Pan-Arctic's platform moved;
25 they had an allowance of twenty feet, and apparently it
26 only moved about eight in, I don't know how many, 5%, I
27 think they were drilling in 450 feet of water, so they
28 could tolerate 5% movement, and they had less than that.
29 So, I think in the Sverdrup Basin, and in the sure fast
30 ice areas, these are areas where the technological

1 problems can be solved fairly quickly, if there was
2 really a mind to get at it and to invest the capital
3 that was necessary.

4 Q We'll be coming to that
5 in a moment.

6 A But it's the moving ice,
7 that I don't see any answer to in my limited under-
8 standing, and some of the things that are being said
9 really frighten me about that moving ice area. At the
10 offshore drilling meeting, senior vice-president of
11 Global Marine said that,

12 "We have given at recent dates some consideration
13 to actually operating or trying to determine the
14 feasibility of operating on the polar ice pack."

15 Q When was that meeting sir?

16 A That was December, 1972,
17 a paper called "Global Marine's Drilling System For The
18 Arctic Offshore." It was by R.B. Thornberg, senior
19 vice-president of Global Marine; and that's the area
20 when you start talking about the polar pack, and even
21 the ice in the Beaufort Sea, it seems to me that in
22 there, there is no immediate answer, and I haven't
23 been able to see any possible - I haven't been able to
24 learn of ^{any} possible approach to the solution of that
25 problem, and I think that is ^{the} paramount one.

26 Q And I take it that you
27 see that as ^{the} paramount problem because of your concern
28 over blowouts from drill ships that may require relief
29 well drilling from the pack ice?

30 A Well, it's the production

1 systems as well. How do you service production systems?
2 If you get 150 miles from shore, it's going to be very
3 difficult, I think Mr. Shearer brought it out yesterday,
4 of getting that petroleum, whatever form it's in, to
5 the shore without doing some kind of treatment; and
6 we have a long long way to go, in even being able to
7 look after some kind of a leak in a system like that;
8 during a difficult time, during a breakup period,
9 during a moving ice period.

10 So I think that the problems
11 there are not just associated with exploratory
12 development drilling but they are very, very big in
13 terms of ^{both} production and transportation.

14 Q Yes. Now sir, I take it
15 that this particular research front, is in your view,
16 the responsibility of industry, rather than government?

17 A Absolutely. The only
18 question I've had in my mind, is whether or not
19 government has some responsibility, given that it has
20 encouraged industry to take out exploration permits
21 in these areas. The first permit in the Beaufort Sea
22 was given in the early 1960's, the bonus blocks were
23 given out in 1968, and given that the industry was
24 encouraged to get out there and to spend a lot of
25 money, I think the question needs to be faced as to
26 whether or not we have some responsibility to advance
27 the technology, to move ahead more quickly on this
28 front. I've asked myself that question a lot of times,
29 and I certainly wouldn't be the one that screamed very
30 loudly if a decision was made that there should be

1 government participation, because as I say, I think the
2 government has a primary responsibility for encouraging
3 industry so strongly to take out exploration permits.

4 Q Well what then, is your
5 answer to your own question, is it that there is any
6 other responsibility for this program besides the one
7 falling on industry?

8 A I left it up in the air
9 because I never answered the question, I've simply said
10 that it has come to my mind many times, and I don't
11 know. I think it would be reasonable to consider it
12 at least.

13 Q Yes. The primary
14 responsibility, however you answer your question though,
15 remains with industry.

16 A That's correct.

17 Q Now, given the three
18 research areas that you've identified and spoken your
19 concern about, if you take them all together and if
20 you assumed research moving forward on those three
21 fronts, can you tell me at all whether there would be
22 a risk reduction in terms of what might happen to the
23 environment? I take it the whole point of these three
24 research front movements is to reduce risk?

25 A What is the question
26 specifically?

27 Q What I'm interested in
28 is, is it possible for you identify, assuming these
29 research programs to move forward as you would like,
30 over the next decade, or something shorter, what order

1 of magnitude in risk reduction are we talking about?

2 A Well, I don't know. If
3 we could operate in the Beaufort Sea on even a nine-
4 month basis, in case of an emergency, it would be very
5 considerable; because then in the case of a blowout
6 we'd have a very good chance of turning it off within
7 two to three months. And now, Dr. Millen suggested,
8 as I said yesterday, the potential time that a blowout
9 could blow is two years, up to two years, or conceivably
10 longer.

11 So if we had this capability
12 of going out there and being there for six to eight
13 months, it would be very, very considerable reduction
14 in the magnitude of the risk .

15 Q It doesn't bring the rest
16 to zero, obviously, there will always be a risk.

17 A Absolutely. I presume
18 we're dealing now with societal trade-offs.

19 Q Yes.

20 THE COMMISSIONER: Dr. Millen
21 is head of the Beaufort Sea project?

22 A Yes. And he just issued
23 his summary report which has been circulated by the
24 Minister of the Environment, or the acting Minister.

25 MR BAYLY: He is the witness
26 that we will be calling next.

27 THE COMMISSIONER: You will
28 be calling Dr. Millen.

29 MR BAYLY: Yes, you will be
30 hearing from him the week after next, I anticipate.

1 THE COMMISSIONER: The week
2 after next?

3 MR. BAYLY: Yes. We will be
4 distributing his evidence hopefully before people
5 disperse this week.

6 MR. GOUDGE: Mr. Commissioner,
7 there seems to be a groundswell for coffee. I've
8 reached a break in my cross-examination. I have
9 somewhat more, not too much, but some more than perhaps
10 the coffee wagon can sustain.

11 THE COMMISSIONER: Oh, very
12 well.

D. Pimlott
Cross-Exam by Goudge

(PROCEEDINGS RESUMED PURSUANT TO ADJOURNMENT)
THE COMMISSIONER: Mr. Goudge?

MR. GOUDGE: Yes sir, just a couple of more areas, if I might. Dr. Pimlott, one of the things that you expressed most concern about in terms of offshore drilling is, as you put it at the top of page 27 of your prepared evidence, "the problem caused by an oil blowout in offshore drilling." Now, let me ask you whether you're aware of any statistics that bear on the frequency of blowouts, generally, or blowouts in offshore drilling?

WITNESS PIMLOTT: Yes, I don't have them immediately at my command. They're -- the statistics are covered fairly well in three publications. The two I mentioned yesterday and then there was a further conference and I've forgotten the title of it. I think I have it. I could dig it out in minute, but there was another conference having to do with marine oil pollution questions that dealt a lot with offshore operations that was, I think, sponsored by the National Science Foundation, again. These three publications do give quite a lot of statistical background on spill frequency. Dr. Millen in his paper suggests a blowout frequency of about one in a thousand and in trying to check that out, I came to the conclusion that he was sort of given a best estimate and that some of the statistics for other areas that I looked at, although I don't have the background data immediately, led me to conclude that it could be argued that one in 500 would be much closer to a frequency. But those data are pretty well covered.

D. Pimlott
Cross-Exam by Goudge

1 Q Let me stop
2 you there for a moment and ask you just so I understand
3 it. When Dr. Millen says "one in a thousand", can you
4 tell me, that's one in a thousand what?

5 A I gather he means one in
6 a thousand wells drilled.

7 Q I see.

8 A And there's another
9 question, of course, there seem to be always those
10 are the statistics. Another very pertinent statistic
11 that seems to me should be calculated is, what is the
12 percentage of successful wells where oil or gas is actually
13 discovered? What percentage of those blowout? It seems
14 to me that that's more relevant or just as relevant
15 as the percentage of total wells.

16 Q You understand, Dr. Millen's
17 statistics to relate to one in one thousand wells,
18 whether they are dry or not?

19 A Yes.

20 Q Yes. Now, you said sir,
21 that in your view the proper or perhaps the more
22 pessimistic view would be one in five hundred?

23 A Yes, I think so.

24 Q Let me ask you how you
25 come to that statistic and why you differ from Dr.
26 Millen?

27 A Well, it had to do with
28 the statistics. I think they're right here.

29 Q I've stolen one of your
30 books.

D. Pimlott
Cross-Exam by Goudge

1
2 A If you will let me take
3 a minute, I will quickly try to --

4 Q Well, I would be inter-
5 ested to know the basis on which you say the more
6 realistic figure might be one in five hundred wells
7 drilled?

8 A Well, the statistics
9 as I recall them were, between --

10 THE COMMISSIONER: Excuse
11 me, Dr. Pimlott, why don't you just take a moment and
12 dig them out. We have --

13 MR. GOUDGE: I have got one
14 of your books, sir.

15 A I will check this one
16 first. I have a paper here that is a rather interesting
17 one that deals with these statistics and the section
18 I referred to is in the book "Energy Under the Ocean"
19 and it starts on page 285 and it is called, the section
20 is "Drilling Accidents".

21 Q Just so I will recall
22 it, sir, "Energy Under The Ocean" is what?

23 A It is a publication that
24 was prepared. It is a technology review of offshore
25 drilling in the outer continental shelf and it was
26 prepared under a grant of the National Science Founda-
27 tion by a group, an interdisciplinary group at the
28 University of Oklahoma. It was one of the first
29 background documents in or one of the first background projects
30 leading up to an extensive leasing program for U.S.
outer continental shelf areas.

D. Pimlott
Cross-Exam by Goudge

1 Q And what is the date on
2 it, sir?

3 A It is, I think it is
4 1970, I believe it is 4, 1973.

5 Q I am sorry, you were
6 about to refer to some statistics that, at a given page.

7 A The paragraph here. "An
8 examination of the drilling and blowout rate over the
9 period, 1953 to 1971 reveals that there were two
10 time periods during which most blowouts occurred. 1956
11 to '60 and 1964 to '69. During these two periods
12 the percentage of new well starts resulting in
13 drilling blowouts was a little less than 0.2%, and
14 so that would be about 1 in 500 for that period.

15 Q Yes, I understand.

16 A One percent would be
17 one in one hundred and .02 would be -- we're dealing
18 in that statistic, that is one statistic which states
19 that.

20 Q Yes, he quotes there
21 though --

22 A There it goes on to
23 say --

24 Q Just so I'll understand
25 before you go on. That is for the two worst periods.

26 A Yes, but then they go
27 on to say, "there appears to have been no decrease in
28 the percentage of blowouts over the years. If only
29 blowouts from wells producing oil and gas are counted
30 for the period, 1964 to 1971, the percentage is 0.3%."

D. Pimlott
Cross-Exam by Goudge

1 Q Yes. Now, do you know
2 whether, I am just interested -- are those statistics
3 on a world-wide basis or on what other basis?

4 A I believe these were
5 all U.S. statistics that they were dealing with.

6 Q Do they include both
7 onshore and offshore statistics?

8 A No, those were just
9 offshore. There is a separate paragraph here which
10 indicates which gives the statistics for onshore and
11 which indicates that there was a lower rate for
12 onshore and it is almost a factor of 10, I believe, in
13 the difference.

14 Q So what you are saying
15 is that for the two time frames estimated, 1956 to '60
16 and 1964 to '69, the experience offshore has been
17 a one in 500 well blowout ratio.

18 A Yes.

19 Q I might say that one of
20 the things that makes it difficult to just use the
21 ordinary statistical procedure is the fact that there
22 seems to be very often this clumping effect with
23 periods --

24 Q This what effect?

25 A I called it a clumping
26 effect. A period of time when for some reasons I
27 don't understand, there is an increased frequency of
28 accidents. There is an article in "Offshore" magazine
29 which deals with storms which indicate that in dealing
30 with mishaps in offshore rigs and that there are some

1 periods of time when there is an increased frequency of
2 accidents so it is -- when you talk about one in a
3 thousand, it seems to me that statistically and I don't
4 pretend to be again a statistical expert, but when you
5 are dealing with a situation where you get variation and
6 not a uniform periodicity then that is a whole new
7 ball game.

8 Q Yes, I see.

9 A Dealing with the statis-
10 tics, if you are -- you seem to be interested in
11 those -- in the period from 1955 to 1974, there were
12 listed that there were 95 serious rig, offshore rig
13 mishaps in the, on the world scale and weather caused
14 46% of those and blowouts caused 22%. 21% of these
15 95 rig mishaps that occurred between 1955 and 1974
16 resulted from blowouts and that is based on an article
17 in "Offshore" magazine and it is called "Storms are a
18 Major Cause of Mobile Rig Mishaps Offshore". It was
19 in June 5, 1974.

20 Q Coming back to the one
21 in 500 risk factor, if I can call it that, would it
22 be your opinion that with advancing technology
23 that figure would be elevated to something like Dr.
24 Miller projects or beyond one in a thousand or perhaps
25 one in an even larger number of wells drilled?

26 A No, I feel very uncertain
27 because about that, granted that there is improved
28 technology or apparently improving technology but there
29 is all of the unknowns of operating in a very harsh
30 physical environment and I don't see how -- I don't

D. Pimlott
Cross-Exam by Goudge

1 feel prepared to make any blanket prediction
2 that is valid. I don't know.

3 Q Well then, let me ask
4 you the next question and you may well decline to
5 answer it as well. Is there any threshold risk level
6 that must be reached before, in your view, this kind of
7 drilling should be permitted, that is, I take it,
8 implicit in your evidence is that the one in 500
9 statistic is unacceptable from your point of view.
10 What would be acceptable?

11 A In my testimony -- the
12 way I ended my testimony, I said "I do not consider
13 that it is in the national interest to put at risk
14 the natural resource base of northern natives peoples
15 and the Arctic environment in this way at this time."
16 And implicit in that is that I, the feeling that I
17 don't like acting or pretending that I am God in
18 trying to say what society should do. What I feel
19 very strongly about is that we should have a much
20 more rational approach to considering the options
21 that are open to us and to evaluating the various
22 areas of societal needs. I want society, I want
23 to do what I can to contribute to society doing a more
24 comprehensive job of coming to terms with this. But
25 I don't, I am not prepared to set a Doug Pimlott
26 standard for what should happen in the Beaufort Sea
27 or what level of risk we should take. I hope I can
28 contribute to us doing more about it but I don't try
29 to set myself up as God in that way.

30 Q Are you prepared though

D. Pimlott
Cross-Exam by Goudge

1 to say that the present risk standard that you have
2 advanced, one in 500 should be deemed unacceptable?
3

4 A Under the present
5 framework, yes, I consider that to be so.

6 Q Yes.

7 A In both --

8 Q Having said that though,
9 sir, aren't you obliged to say what risk standards
10 you would see as acceptable?

11 A No, I'm not because
12 if we had come to -- if society by some more rational
13 process, if even the members of the House of Commons
14 had gotten together and said, "look, we must have this
15 oil for this reason," I think I could be convinced.
16 Maybe we do, but we have not gone through any rational
17 approach to deciding about whether this was
18 a good option for us at this time, either in terms
19 of the other areas of societal concern, in terms of
20 the needs of the next generation for petrochemical
21 products and that is why I said, "in this way at this
22 time." Perhaps it is an acceptable, if our needs are
23 great enough. I am impressed by the fact that five
24 years ago the industry was telling us that we had
25 oil and gas for a multiple of decades and I must
26 confess that I am a doubter, I don't know whether the
27 industry is giving me, selling me a bill of goods now
28 or not. I would like to know that. And I would like
29 to see our society answer some of these questions so
30 those of us who are concerned would understand what

D. Pimlott
Cross-Exam by Goudge

1 kinds of trade-offs we logically should be willing
2 to accept.

3 THE COMMISSIONER: Well, they
4 said we had 300 years of gas and a thousand years of
5 oil. Now, it appears they do not claim to that same
6 view. But the National Energy Board is currently
7 holding hearings at which they are examining the
8 questions that you have raised. They are important
9 questions; that is, do we have to bring this gas from
10 the frontier. That is, do the needs of southern
11 Canada require it and I have said that the Cabinet
12 will, at the end of the day, have my report before
13 them which will indicate the impact that the pipeline
14 and all that it will mean, would have on the north, and
15 at the same time they will have the Energy Board's
16 report which will indicate what the supply of gas
17 may be in the Western Arctic and what the demands of
18 the Canadian market and perhaps the U.S. market are,
19 and then they will have to decide. But you may say
20 that all of this will come later than it should have,
21 but that appears to be the kind of decision making
22 process the government has sought to organize.

23 Certainly, if you compare
24 it to the decision making process that has attended
25 large scale frontier developments in the past, it
26 must compare favourably, at least, in some limited
27 respect. I hope it does after all this. At any
28 rate, I understand the point you are making. I'm just
29 introducing a word of --well, praise is too extravagant
30 an expression when dealing with the Federal Government

1 capability of understanding and the decisions for
2 this should not be made in camera, but I really, I
3 would love to praise for a change but --

4 THE COMMISSIONER: Well, we
5 will all look forward to that.

6 MR. GOUDGE:

7 Q May I move, Dr. Pimlott,
8 really from the sublime to the ridiculous? I would
9 like to ask you one or two more questions about the
10 statistics that you have knowledge of. You have
11 told us about your -- some of the statistics
12 that relate to blowouts offshore and I understood you
13 to say that there are statistics available for
14 blowouts onshore and they show a substantially reduced
15 frequency of blowouts onshore.

16 A Yes, that is --

17 Q Where are they in that
18 book?

19 A Page 268, the last
20 paragraph of that drilling accident section that I
21 referred --

22 Q And that is the same
23 book, for the record, that you were referring to a moment
24 ago.

25 A Yes, that's right.

26 Q Now, are there statistics
27 in that book or elsewhere to your knowledge that
28 relate to the time taken for the drilling of relief
29 wells in a blowout situation?

30 A No, we have some
31 Canadian statistics available in terms of King

D. Pimlott
Cross-Exam by Goudge

1 Christian Island and I have -- I'm not sure I
2 totally recall exactly where that piece of paper is,
3 but I do have the article here on the table which
4 discusses the time frame which is required to drill
5 the relief well for King Christian Island which is a
6 land operation. It was very considerable. It was
7 a land well and as I recall, even there, it was a
8 six-month operation by the time the equipment was
9 assembled and all of the problems went through but
10 I don't -- I am not aware of those statistics. I am
11 sure that they are probably available in one of these
12 areas.

13 Q Particularly, perhaps
14 in relation to offshore drilling off the Gulf of Mexico
15 for example?

16 A Yes, and for all of the
17 Southern United States, I think, they would be
18 available.

19 Q Dealing with that, do
20 you know whether there is any requirement or practice
21 that requires the presence of a second drilling
22 platform, back-up drilling platform?

23 A Well, when you get a
24 place like the Gulf of Mexico where you have a very
25 large number of wells being drilled at any one time,
26 they are always available and I -- the answer is
27 no to your question. I can see the -- what I was
28 starting to say was, that I can see the reason for it
29 in places like that because there is usually a multiple
30 of wells being drilled.

D. Pimlott
Cross-Exam by Goudge

1 Q So, it is "no" with
2 an explanation.

3 A Yes, that's right, yes.

4 Q Let me move then, if
5 I can, unless you have not completed your answer, let
6 me move to a matter of spills as opposed to blowouts.

7 A Yes.

8 Q On page 36 of your
9 prepared evidence, you recite that statistics parti-
10 cularly related in the middle of the page to spills
11 from platform drilling?

12 A Yes.

13 Q And do you have any
14 views as to the transferability of those statistics
15 to drilling either from man-made islands or for drilling
16 from ships?

17 A I guess the -- probably
18 the only view I have is that -- has to do with problems
19 associated with, the likely problems associated with
20 the incident and I am referring to the ice conditions
21 that we have been introduced by Mr. Shearer and
22 which I have referred. It would seem that even the
23 same number of spills could probably constitute a
24 larger problem in the Beaufort Sea because it would
25 be much more difficult to deal with and because we
26 probably couldn't get down say to a leaking well head
27 if it occurred at the break-up or the freeze-up to
28 repair it, so I'm inclined to think that the same
29 number of problems would create a greater total
30 problem but I don't have any --

D. Pimlott
Cross-Exam by Goudge

1 Q I understand your
2 views on that score. I was simply asking whether you
3 had any opinion as to the transferability of the
4 numbers.

5 A I think that -- my
6 guess again would be that they would be conservative
7 for the Beaufort Sea because of the problems associ-
8 ated with brittle fracture of metals and things like
9 this at low temperatures. I am inclined to think
10 that they should be considered to be quite on the
11 conservative side, but again I am no engineer and I'm
12 not sure whether logic takes us very far.

13 Q You say though, at the
14 bottom of page 36, that one of the difficulties with
15 the spill problem is the enforcement aspect of it, the
16 problem of prosecuting offenders. I wonder if you
17 have given any thought to more effective ways of
18 enforcing spill, anti-spill regulations.

19 A No, it is a very
20 difficult problem. It is particularly difficult
21 under a regulatory system where both the exploration
22 and the environmental aspects occur in the same
23 department and because the adequate emphasis is rarely
24 placed on environment and when a company is in a
25 difficult economic position, they will often, they
26 will sometimes take the action and then face the
27 consequences later as the lesser evil that they have
28 to do with. There have been some examples of that in
29 the Beaufort Sea and one particular one which I don't
30 think I have the specific documentation but it had

D. Pimlott
Cross-Exam by Goudge

1 to do with a company which was building an island. It
2 found that its gravel source was inadequate and then
3 it took action to go to an island and withdraw gravel
4 without a permit and as I considered that action it
5 was one of, as far as the company was concerned, it
6 was a lesser evil. It faced the consequences rather
7 than holding up its operation and I think that that
8 applies -- when you have that kind of thing coming under
9 control of a department that has the conflict of
10 interest, it makes it difficult to get balance in
11 regulatory process.

12 Q So that is one principle
13 that you are suggesting in the enforcement of any
14 anti-spill regulations, a separate enforcement agency?

15 A This is something which
16 the industry doesn't want and you go back over the --

17 Q Well, is it desirable
18 from your point of view?

19 A Very desirable, yes, I
20 think it is one of the complications in industrial
21 processes that has to be, that should be tolerated.

22 Q Are there any other
23 alterations in the present system that relate specifi-
24 cally to enforcement that you would see as producing
25 a more efficient enforcement of anti-spill regulations?

26 A I'm always distressed
27 by the fact that things like this are kept secret and
28 I feel very strongly that there should be more open
29 process so that the problems which come to the
30 surface are known to the public and I think in the

D. Pimlott
Cross-Exam by Goudge

1 kind of the system that we live in, it works better
2 when things are discussed, dealt with openly,
3 so the second principle that I would enunciate would
4 be this one of much more regular much more open
5 process and particularly with respect to enforcement.
6 The publication of all things that are associated with
7 infractions of regulations.

8 Q Those are two basic
9 principles that -- I take it those would be the
10 two main ones.

11 A Well, I feel a little
12 bit like that TV show where you -- I have gotten
13 \$10.00 and ^{will} I go for 20. The other aspect, I guess,
14 that -- one of the other areas that I think is
15 unfortunate and difficult -- it poses difficulty
16 in, particular difficulties in the north, is the
17 relationship between legislation and regulation.
18 In our legislation, we give tremendous power to the
19 administration to make regulations which are not
20 subject to review at all by members of parliament, and
21 that problem has been shown very clearly in the processes
22 that we are going through with respect to the revisions
23 of the oil and gas plant regulations. Here we have
24 a process that is going on. There is a regular
25 interchange between the industry and government of the
26 revised regulations and seeking comments of industry,
27 but the members of parliament have no access to this
28 and the members of parliament will never have an
29 opportunity, the appropriate committee of the Commons,
30 will never have an opportunity to have any input on the

D. Pimlott
Cross-Exam by Goudge

1 new oil and gas plant regulations and I guess the
2 third principle if I were to enunciate it and I think
3 I will stop at this one.

4 Q I don't have more than
5 \$20.00.

6 A -- Is that, I think there
7 should be much more-in dealing with the basic legislation
8 and regulations, there should be much more involvement
9 in terms of political, direct political process. We
10 had a conference in Ottawa early in December and one
11 of the things that, we had an official of the Norwegian
12 government there and the one thing that came out very
13 strongly to my mind and to my inclinations was the fact
14 that all major things associated with offshore
15 development are made matters that are well-known by
16 all Members of Parliament. I mentioned yesterday that
17 the incongruity of a Member of Parliament for the
18 Northwest Territories learning first about offshore
19 drilling from COPE, rather than as part of his function
20 as a Member of Parliament. And in terms of the whole
21 question of dealing with these regulations, there should
22 be much more involvement of parliament.

23 Q You are starting to
24 like Mr. Diefenbaker, Dr. Pimlott. Finally, let me
25 ask you a couple of questions relating to your evidence
26 on page 20 of your prepared evidence, where you referred
27 to the problem of abnormal geological pressures --
28 high geo-pressures. You expressed that as a concern
29 in drilling in the Beaufort Sea and I take it your
30 concern there is that there may be a coincidence between

D. Pimlott
Cross-Exam by Goudge

1 the occurrence of high geo-pressures and a blowout.

2 A Yes. That is correct.

3 Q I wonder if you are aware
4 of any statistics or records that relate to accidents
5 caused by high geo-pressures.

6 A I tried very hard to
7 become well-informed on the question of geo-pressures in
8 trying to do the background research and I found it
9 was a subject which wasn't well-covered at all and
10 there seems, technologically, as I think Mr. Horsfield
11 pointed out, industry is getting used to handling
12 them but there is no question in my mind that they do
13 pose a hazard, an additional hazard, because as they
14 go from one layer, one geological formation to another
15 they pose the threat of the system having to adapt
16 quickly to changing pressures and it is a real
17 intricate game that has to be played, because the balance,
18 the pressures that exist in the formation have to be
19 counterbalanced by the mud weight but they can't over-
20 compensate with the mud because if they run into a
21 weak geological formation, then they impregnate that
22 formation with their mud and they lose it and so then
23 they can get a rebound of the pressure and so they can't--
24 they have to play a very careful game and I think
25 Immerk is the evidence.

26 Q Yes, I understand that,
27 sir, and that is helpful but I am interested in knowing
28 whether you know of any series of records on accidents
29 due to high geo-pressures. No doubt, --

30 A They are simply, as far as

D. Pimlott
Cross-Exam by Goudge

1 I am concerned, it is a question very much like
2 seismic. It has never been adequately dealt with in
3 the literature. I went to Ohio State University where
4 there was supposed to be one of the authorities and I
5 have the reference, I will just take a moment to locate
6 the citation here, there was a paper by R.A. Deju.
7 It was called "A World-wide Look at the Occurrence of
8 High Pressure, High Fluid Pressures in Petroliferous
9 Basins" and that was Wright State University, Department
10 of Geology in 1973, Wright State University is in
11 Ohio. That paper was supported by the petroleum
12 industry, but it gave a rather interesting look at the
13 problem as exist in different basins but it didn't give
14 any statistics at all. There is just nothing given
15 anywhere in the literature that I could discover and
16 I went to Dr. Ken North. I had him criticize my
17 original manuscript. I asked his advice and he is
18 a petroleum geologist and he couldn't identify any
19 other literature. In fact, I had encountered, dug up
20 some that he was not aware of. It just doesn't seem to
21 exist.

22 Q I take it though that you
23 acknowledge that any risk or any increased risk
24 presented as a result of high geo-pressures is to some
25 degree at least, mitigated by what you acknowledge to
26 be the caution of exploratory drillers?

27 A I'm sorry. I --

28 Q Well, let me begin by
29 saying that on page 37 of your prepared evidence, I
30 understood you to say that there is to some degree at

D. Pimlott
Cross-Exam by Goudge

1 least, evidence of caution used in exploratory drilling.

2 A Yes, I was impressed by
3 what I heard was happening. It seemed to me that it was
4 done with care.

5 Q Yes, and that that
6 caution provides counterweight, to some degree at least,
7 to risks presented by high geo-pressures.

8 A I think that is the case,
9 yes.

10 Q And what must be done
11 is to take into account in planning and in estimating
12 risk this factor of high geo-pressure?

13 A Yes, but it still
14 results in increased risk.

15 Q Yes, I appreciate that,
16 sir. Those are all the questions I have, Mr. Commis-
17 sioner, of Dr. Pimlott.

18 THE COMMISSIONER: Any re-
19 examination?

20 MR. BAYLY: No re-examination,
21 Mr. Commissioner. I see it is 25 past 12 and I would
22 suggest that we not start not Dr. Martell's evidence
23 until 2:00.

24 THE COMMISSIONER: Right, well,
25 thank you very much, Dr. Pimlott. We certainly have
26 gained from your discussion of these problems and I
27 mean the matters of environmental impact that you have dealt
28 with. I make no comment on the reflections that you
29 offered on the decision-making process that the
30 government has followed in connection with the

1 proposed offshore drilling. I wonder if you would
2 let Mr. Goudge and Dr. Fyles just look at the
3 material that you have in front of you, and perhaps
4 any documents that they wished copies of or wished to
5 be introduced as exhibits might be -- arrangements
6 might be made for them to be photocopied by the
7 Inquiry so --

8 WITNESS PIMLOTT: If I might say,
9 sir, in addition to this book, I have other documents
10 and there are some of these that are, as far as I am
11 concerned, I would be quite willing to make available
12 to the Commission. I have no immediate -- I have
13 finished the immediate job and in the whole question
14 of risk, there is a supplementary volume entirely
15 dealing with that and so I would be glad in any of
16 these documents to have them deposited with the
17 Commission.

18 THE COMMISSIONER: Thank you,
19 Dr. Pimlott. Well, we'll adjourn till 2:00.

20 (WITNESS ASIDE)

21 (PROCEEDINGS ADJOURNED TILL 2:00 P.M.)

22 (PROCEEDINGS RESUMED PURSUANT TO ADJOURNMENT)

23 ARTHUR M. MARTELL, sworn:

24 MR. GOUDGE: Perhaps, sir,
25 before we begin the evidence of the next witness, could
26 I tender as exhibits three documents which Dr. Pimlott
27 has been good enough to leave with us and on which he
28 relied. The first is a document entitled "Energy
29 Under the Oceans, A Technological Assessment of
30 Outer Continental Shelf, Oil and Gas Operation "

1 ("ENERGY UNDER THE OCEANS", KASS, WHITE AND OTHERS,
2 MARKED AS EXHIBIT NO. 442)

3 MR. GOUDGE: The second is
4 a document entitled "O.C.S. Oil & Gas - An Environmental
5 Assessment", which was a report to the President by
6 the Council on Environmental Quality in the United
7 States, dated April, 1974, and that's volume 1.

8 ("O.C.S. OIL & GAS - AN ENVIRONMENTAL ASSESSMENT",
9 VOLUME 1, APRIL, 1974, MARKED AS EXHIBIT NO. 443)

10 MR. GOUDGE: And the third
11 document is entitled "Arctic Well Control Contingency
12 Plan - Edmonton Alberta", dated January 1, 1973.

13 ("ARCTIC WELL CONTROL CONTINGENCY PLAN", JANUARY 1
14 1973, MARKED AS EXHIBIT NO. 444)

15 MR. GOUDGE: If I could tender
16 those three documents, please.

17 THE COMMISSIONER: Right.

18 MR. BAYLY: Mr. Commissioner,
19 just before beginning Dr. Martell's evidence, I've
20 distributed the evidence of Dr. Allen Millen, to the
21 participants here, and it will be mailed out to the
22 other participants at some point today or tomorrow.

23 CROSS-EXAMINATION BY MR. BAYLY:

24 Q: Dr. Martell, I understand
25 you've been sworn, and I wonder if you could turn to
26 your curriculum vita attached to your evidence, and
27 go through it for the Commission, please.

28 WITNESS MARTELL: I received
29 my Bachelor of Science degree in biology at Acadia
30 University in Nova Scotia, in 1967, and I continued at
the same university to do a study on wintering water-

A.M. Martell
In Chief

1 fowl, in a sanctuary area in Nova Scotia where I was
2 to assess a management plan in relation to both
3 hunting effects in the area and the effects of various
4 environmental conditions.

5 I then went to the University
6 of Alberta and did my doctoral work here in Mackenzie
7 delta area, on tundra and forest populations of
8 northern redbacked voles.

9 My professional experience
10 dates just from 1966 when I did some work on the
11 American dog tick in Nova Scotia, then did a summer's
12 work on Atlantic mackerel with Fisheries' Research
13 Board, my waterfowl work in relation to thesis work.

14 I did one summer's research
15 and subsequently some later winter research and lab
16 research leading to papers, on collared lemming on
17 Devon Island. It's part of the International
18 Biological Program, Tundra Biome.

19 While I was doing my doctoral
20 research here, I also did some research on the effects
21 of oil exploration activities on tundra small mammals,
22 and tundra plant communities, on the upland shrub areas
23 east of the Mackenzie delta, and this was done for
24 Imperial Oil.

25 Following that, I worked for
26 a year as a research associate of the Boreal Institute
27 for Northern Studies, the University of Alberta. While
28 working in that, as well as being involved in teaching
29 a short course for A.R.M.O. program with Indian Affairs
30 and being involved in a renewable resource mapping

A.M. Martell
In Chief

1 project, the main part of my work there was involved
2 in doing a literature review primarily, on the wildlife
3 in the delta area, and this was to be written up in a
4 form that would be usable by non-science people, but
5 still try to incorporate enough of the references and
6 hard data that it could be used as a scientific
7 reference as well. This is the document to which I
8 refer, this is about to go to Indian Affairs, it should
9 have been there six months ago, but due to certain
10 contingencies out of my control since I left there
11 last June, it's just - I finished it off this fall at
12 the request of the acting director, and it will be going
13 to Indian Affairs, and I suppose if the Inquiry after
14 I present my evidence were interested in it, it can be
15 obtained through Barry Yates, at Indian Affairs in
16 Ottawa.

17 Presently I am working as
18 a research scientist for the Canadian Wildlife Service,
19 Sault Ste. Marie, working on small mammals in relation
20 to forest regeneration in Ontario. And attached are a
21 list of publications that I have been involved in.

22 MR. BAYLY: Dr. Martell, I
23 understand that we've shuffled your bibliography
24 incorrectly, -

25 A Yes, I found when it got
26 here, while it was being copied here, I guess, it has
27 been shuffled around, so if you'd refer to the printed
28 material, and take pages 27 to 31, and place those in
29 front or following page 20, it then puts it back into
30 the proper order. In other words, the page that says

A.M. Martell
In Chief

1 "reports referred to or relied on", and it makes
2 reference to this report on the wildlife in the
3 MacKenzie delta region, the following sets of literature
4 cited then, are taken directly from the material,
5 from the report, and refer to sections on fish, birds
6 and mammals, respectively.

7 Q I wonder if we could
8 turn then, Dr. Martell, to the first page of your
9 evidence, and if you could begin by giving your
10 evidence to the Inquiry, if you could begin by giving
11 this evidence to the Inquiry?

12 A Right. I've titled the
13 evidence "The Mackenzie Delta Wildlife - An Historical
14 Review Of Man's Impact".

15 When we speak of the "Mackenzie Delta Area" in
16 terms of people and wildlife we cannot consider only
17 the modern delta of the Mackenzie River. Before the
18 arrival of the Europeans the modern delta itself was
19 little used relative to the surrounding areas, and,
20 even with increased centralization of settlement, the
21 people of the area ranged widely in their routine
22 travels. This larger area may reasonably be considered
23 to extend from the modern Mackenzie Delta west to
24 Herschel Island and Lapierre House, south to the
25 Fishing Lakes and Little Chicago, and east to Cape
26 Bathurst and the forks of the Anderson River, and it's
27 to this larger area that I will refer to as the
28 Delta Area.

29 People probably first moved into the Delta area
30 shortly after the end of the Wisconsin Glaciation,

1 or at least 10,000 years ago. These people used the
2 wildlife resources of the region as the basis of their
3 livelihood , and continued to do so unimpeded for the
4 next few thousand years. The entrance of Europeans into
5 the region in 1789 (Alexander Mackenzie's expedition),
6 was also prompted by the wildlife of the region, but
7 in this case money making wildlife - fur.

8 Although there was some fur trade in the Delta
9 area through old Fort Good Hope between 1823 and 1826,
10 and Old Fort Good Hope was located quite near Little
11 Chicago at the bend in the Mackenzie River, fur trade
12 in the region really developed only after the
13 establishment of Peel's River Post (Fort McPherson) in
14 1840, Lapierre House in 1845, and Fort Anderson in 1861.
15 Fur remained the main economic base of the Delta economy
16 until bowhead whaling replaced it between 1889 and 1910.
17 During this period the Delta area was the Centre of the
18 whaling industry in the the eastern Beaufort Sea and
19 served as the winter port for a good portion of the
20 Arctic whaling fleet; the Arctic Whaling Fleet is
21 commonly referred to as such, and refers to the fleet
22 sailing from San Francisco, the American whaling fleet.
23 74 ships wintered at Herschel Island and at least 24
24 ships wintered between Toker Point and Langton Bay.
25 After 1910 there was an expansion and intensification
26 of the fur trade, particularly noticeable in the 1920's.
27 This boom eventually tapered off, however, and during
28 the last 10 to 15 years, industry based on oil and gas
29 exploration has become the main base of the Delta
30 economy. It is probable that industry based on oil and

A.M. Martell
In Chief

1 gas exploration and the development of reserves will
2 continue to be the base for the next few decades.

3 Recently much concern has been expressed by Delta
4 residents and other environmentally conscious
5 groups over the impact of petroleum exploration and
6 development activities on the wildlife of the region.
7 This concern is not surprising when one considers that
8 the wildlife resources have been the mainstay of the
9 Delta economy for all but about 10 of the last 10,000
10 years.

11 Recorded information on the wildlife of the Delta
12 area began with the explorer, Alexander Mackenzie, in
13 1789. Casual observations were made by the second
14 Franklin expedition, by Franklin and Richardson, in 1825
15 and 1826, and by the Franklin Search Expeditions,
16 (Armstrong, Hooper, McClure, Miertsching, Nelson, Pullen,
17 and Richardson), between 1848 and 1853. The most
18 notable of these explorers was John Richardson who made a
19 few biological collections in the Delta Area in 1826 and
20 1848.

21 The early fur traders, Isbister, MacFarlane, and
22 Ross, made somewhat more detailed observations on the
23 wildlife of the region, as it was the basis of their
24 livelihood. The most noticeable of these was Roderick
25 MacFarlane, who explored the Anderson River in 1857
26 and 1859 and established and operated Fort Anderson
27 between 1861 and 1864. During this relatively short
28 period, MacFarlane collected thousands of specimens
29 of birds and mammals in the Anderson River and Bathurst
30 Peninsula area. These collections formed the basis

1 of our knowledge of the wildlife of the region for the
2 next fifty to seventy-five years, and in fact, some of
3 MacFarlane's collections are still the only collections
4 in certain parts of the Delta region.

5 The missionaries began
6 activities in the Delta Area about 1860, but the only
7 missionary notable for his observations on wildlife was
8 Father Emile Petitot who was active in the region
9 between 1865 and 1872. The whalers were active in the
10 Delta area between 1889 and 1910, but were generally
11 more interested in bowhead whales than in other
12 wildlife. However, a few of them, Bodfish, Cook,
13 Klengenberg, and Pedersen, made general observations.

14 A number of explorers visited
15 the Delta Area between 1889 and 1907: Harrison, Preble,
16 Russell, Sainville, Seale, Stefansson and Stone, and
17 most of them made observations on the wildlife of the
18 region; in fact, several of these expeditions were
19 specifically designed for collection of information on
20 wildlife. Between 1908 and 1918, two significant
21 expeditions visited the Delta area: the Stefansson-
22 Anderson expedition of 1908 to 1912, and the
23 Canadian Arctic Expedition of 1913 to 1918. Largely
24 through the work of Rudolph Anderson, these
25 expeditions gathered much basic information on the
26 birds, mammals and fish of the region. Anderson's
27 work formed the best basis of information on the
28 wildlife of the Delta Area since that of MacFarlane,
29 and this information was largely non-overlapping as
30 they concentrated their work in different parts of the

A.M. Martell
In Chief

region. Two other expeditions passed through the Delta Area in the early part of this century and made casual observations on wildlife: the Gjoa Expedition of 1903 to 1907, and the Fifth Thule Expedition of 1921 to 1924.

Between 1927 and 1935, Alfred Porsild worked in the Delta Area, particularly near the modern Mackenzie Delta. And again, primarily in areas non-overlapping with those areas worked by Anderson and MacFarlane. He gathered the best information on the wildlife of the region from its discovery in 1789 until after the Second World War. But this information, gathered by MacFarlane, Anderson and Porsild, along with the many casual observations of other visitors to the Delta Area, is the sum of our documented knowledge of the wildlife of the region for the first 150 years after its discovery. For the most part, however, this information consists merely of lists of the animals found in the region, and some natural history observations. Little was known either of the detailed ecology of the Delta Area or of any of the animal species found there. There is, therefore, no real way of evaluating the impact of man's activities during that period.

There were two major sources of disturbance to the wildlife of the Delta region prior to about 1960: the fur trade and the whaling industry. Both of these, especially the whaling industry, were intensive programs designed to extract resources from the region with minimal cost and maximum profit. Little or no thought was given to long-term planned harvesting

A.M. Martell
In Chief

1 of these renewable resources until relatively recently,
2 when controlled fur harvests were begun.

3 Hundreds of thousands of
4 muskrat, beaver, marten, mink, wolverine, lynx, fox,
5 and other fur bearers have been harvested in the Delta
6 area since the establishment of the fur trade. That
7 populations of these species still exist, despite the
8 trapping pressure, cannot be taken as evidence that
9 trapping has had no impact on them. However, it is
10 virtually impossible to determine what the impact has
11 been as no data is available on the populations prior
12 to trapping and few studies have been done since.

13 One exception to this general
14 case is the beaver. According to Knud Lang, 1867 was
15 the last year beavers were taken in large numbers in
16 the Mackenzie Delta area, - I should mention Knud Land
17 was a fur trader that worked in the Delta Area for many
18 years and had quite a bit of practical experience in
19 terms of the fur trade - but they were still fairly
20 numerous 1900 to 1910. Populations then declined and
21 the beaver was scarce by about 1925 and remained so
22 until the Beaver Sanctuary was established in 1940.
23 With protection, beaver apparently increased or did
24 increase apparently with protection I should say,
25 sorry, and by 1947 there was a small scattered
26 population on either side of the modern Mackenzie Delta.
27 The increase was particularly noticeable after 1949,
28 and with minor fluctuation, remained high until 1965.

29 This general pattern suggests
30 that the decline in beaver populations was the direct

A.M. Martell
In Chief

1 result of overtrapping. However, other historical
2 information does not confirm this pattern. Mackenzie
3 inquired about various animals when he met a group of
4 Indians near the outlet of Travaillant Lake in 1789
5 but reported:

6 "As for the beaver, the existence of such a
7 creature does not seem to be known by them."
8 Beaver were not mentioned by several other early
9 travellers on the lower Mackenzie River and the modern
10 Mackenzie Delta: Franklin, Hooper, Isbister, Pullen,
11 and Richardson, but Richardson did report the beaver
12 inhabited the shores of the Mackenzie River to 67 1/2°
13 or 68° North, and MacFarlane reported beaver on the
14 Carnwath River in the vicinity of Fort Anderson. This
15 suggests that beaver may never have been very abundant
16 in the Delta area. The historical data base therefore
17 is inadequate to explain beaver population fluctuations
18 in the region.

19 Beaver in the Delta area,
20 however, have been studied by Canadian Wildlife Service
21 personnel, principally Vern Hawley. These studies
22 documented a sharp decline in the beaver population
23 between 1965 and 1970, and found that the decline was
24 associated with a degradation of food supplies rather
25 than overtrapping. This suggests then, that past
26 fluctuations in beaver numbers may also have been more
27 related to food supplies than to trapping pressure,
28 although, on the other hand, trapping cannot be entirely
29 ruled out. It leaves us then at an impasse, in deciding
30 the cause of beaver fluctuations.

A.M. Martell
In Chief

1 The whaling industry produced
2 a more clear-cut impact on the wildlife of the Delta
3 Area, and not only to bowhead whales. The whalers
4 utilized large numbers of caribou, Dall sheep, moose,
5 muskox, rabbits, ptarmigan, and waterfowl for food.
6 Only their impact on bowhead, caribou, and muskox has
7 been noticeable.

8 Between 1889 and 1910 a total
9 of at least 98 ships wintered in the Delta region:
10 74 at Herschel Island, at least 14 at Cape Bathurst
11 and Baillie Island, 9 at Langton Bay, and 1 at Toker
12 Point. Each of these ships had about a 50-man crew,
13 about ten to twelve Inuit hunters, and twenty to fifty
14 dogs. These ships relied heavily on the wildlife of
15 the Delta Area for winter meat supplies. Based on
16 whalers' accounts and other available information,
17 each ship used an average of about 13,500 pounds of
18 game meat per winter, primarily caribou.

19 THE COMMISSIONER: When you
20 say, Dr. Martell, that a total of 98 ships wintered
21 in the Delta between 1889 and 1910, you mean over that
22 period of time, altogether?

23 A This is^a accumulative
24 number, yes.

25 Because of the distance^{this} /game
26 was hunted from the ships, normally only the saddle
27 of the caribou, or the area toward the lower back and
28 hindquarters where the meat's concentrated, was brought
29 in; these weighed an average of 31.5 pounds. Therefore
30 we can estimate, between 1890 and 1908, whalers wintering

1 at Herschel Island harvested at least 32,000 caribou,
2 an average of 1,800 per year, primarily from the
3 Porcupine Herd, and between 1897 and 1910, whalers
4 wintering east of the modern Mackenzie Delta harvested
5 at least 10,000 caribou, primarily from the Bluenose
6 Herd.

7 Because of the lack of baseline
8 data, it is virtually impossible to estimate the
9 magnitude of the impact of these harvests on the
10 caribou herds. It is likely, however, based on present
11 data information on the Porcupine Caribou Herd, that
12 the harvest had negligible effect on the herd as a
13 whole. However, Knud Lang observed that after the
14 whalers, people had to travel far inland to hunt caribou,
15 and not until 1926 did caribou reappear in the foothills
16 west of the modern Mackenzie Delta. It is possible then
17 that the whalers' harvest affected the portion of the
18 herd which normally winters in the northern parts of
19 the wintering range, but this is only conjecture in the
20 absence of good baseline data.

21 It is more likely that the
22 whalers affected the portion of the Bluenose Herd
23 using the Delta area. Early explorers between 1827
24 and 1853, reported caribou on the Caribou Hills; on
25 Ellice, Kendall, and Richards Islands; and along the
26 Arctic coast of the Tuktoyaktuk Peninsula. Caribou
27 were still reported as common in these areas in the
28 1890's, but were observed to be declining rapidly by
29 the early 1900's. This population was never very large
30 and the harvest of at least 10,000 animals in only

A.M. Martell
In Chief

1 thirteen years must have reduced the stock considerably
2 and may thereby have altered traditional migration
3 patterns. Porsild noted,

4 "In many places on the Caribou Hills and in the
5 Eskimo Lake basin deep-worn trails were still clearly
6 visible in 1927 and 1928, and testified to the former
7 presence of numerous caribou."

8 The Bluenose Herd presently uses only a portion of its
9 former range in the Delta area. Until about ten years
10 ago, its range was essentially restricted to areas
11 east of the Anderson River, but since that time it has
12 been expanding westward at least to the Kugaluk and
13 perhaps to Travaillant Lake area. Again, in the
14 absence of firm baseline data, an estimation of the
15 impact must remain conjectural.

16 The whalers also hunted
17 muskoxen for winter food supplies. Information on
18 either the original status of muskox in the Delta area,
19 or the actual harvest by whalers is very scant.
20 MacFarlane reported that in the 1850's, muskoxen were
21 uncommon between the Mackenzie and Anderson Rivers, but
22 were common east of the Anderson River. Originally,
23 muskoxen were probably little hunted by the inhabitants
24 of the Delta area, but, after the establishment of
25 Hudson Bay Company posts, many hides were brought in
26 for trade. Anderson reported that by 1890, muskoxen
27 had been extirpated west of the Anderson River. The
28 actual arrival of the whalers brought new pressures
29 to bear on the remaining stocks. Bodfish, a whaling
30 captain, who wintered at Langton Bay 1897 and 1898,

A.M. Martell
In Chief

1 and Baillie Island 1898 and 1899, and 1900 and 1901,
2 noted that,

3 "While we wintered in the Arctic, they," referring
4 to the Inuit's hunting for the whaling ships, "killed
5 all the muskoxen in an area of 150 miles."

6 By the early 1900's, muskoxen were extirpated from the
7 Delta region and the western boundary of their
8 distribution was far east of the Anderson River. It
9 is quite likely that man's activities were largely
10 responsible for the loss of muskox from the fauna of
11 the Delta region.

12 The impact of the whalers on
13 the bowhead whale stock is the most conspicuous case
14 of man's disturbance to Delta wildlife. Traditionally,
15 the Nuvorugmiut living on the Tuktoyaktuk Peninsula,
16 and the Avvagmiut on Bathurst Peninsula hunted bowhead,
17 probably taking small, immature, animals. Richardson
18 encountered bowhead hunters at Cape Bathurst in 1848
19 and reported,

20 "In some summers they kill two black whales, very
21 rarely three, and sometimes they are altogether
22 unsuccessful."

23 McClure reported that hunters at Warren Point in 1850
24 had taken three bowhead that season, and MacFarlane
25 noted that the Anderson River Inuit in the 1860's
26 succeeded most seasons in killing one bowhead, but
27 seldom as many as two. Petitot met an old hunter in
28 1868 who had killed only seven bowheads in over 50
29 years as a hunter. Clearly the hunting pressure on
30 the eastern Beaufort Sea bowhead population by Inuit

A.M. Martell
In Chief

1 was minimal. The impact of the American whalers is in
2 sharp contrast to this.

3 The whalers operated in the
4 Delta area mainly between 1889, when the first ships
5 reached Herschel Island, until about 1906 when the
6 price of whalebone dropped drastically and made Arctic
7 whaling unprofitable. Relatively few whales were
8 taken between 1889 and 1892 or after 1900; the peak of
9 the hunting occurred in the intervening seven years,
10 1893 to 1899. In 1908, Inspector Jarvis of the
11 North-west Mounted Police, Herschel Island Detachment,
12 estimated that 1,345 bowheads were killed in Canadian
13 waters between 1889 and 1907, and this appears to be
14 a reasonable estimate. At least another 100 bowheads
15 were taken in the Delta area between 1908 and 1915.
16 Therefore, in only 27 years, and primarily in only
17 seven years, almost 1,500 bowheads were taken in the
18 eastern Beaufort Sea. Today only about 100 bowheads
19 summer in the eastern Beaufort Sea. This tremendous
20 reduction in the bowhead whale stock is almost certainly
21 entirely due to the whalers.

22 We have, then, several cases
23 of possible disturbance to Delta Area wildlife as a result
24 of man's activities. Only in the case of the bowhead
25 whale is man clearly the culprit, although he is highly
26 suspect in the cases of caribou east of the modern
27 Mackenzie Delta and muskoxen. How detectable would
28 these disturbances have been at the time they were
29 occurring? I suggest that in several of the cases we
30 would not have known the magnitude of the disturbance

A.M. Martell
In Chief

1 until it was very great due to the lack of solid baseline
2 data. The question I would now like to raise is
3 whether we are really any better off today in being
4 able to assess disturbance to wildlife populations in
5 the Mackenzie Delta Area.

6 After the Second World War
7 more detailed studies began on the wildlife of the
8 Delta Area, particularly on the economic species such
9 as beaver, muskrat, and waterfowl. During the last
10 ten years, probably more manpower has been expended
11 in the study of wildlife of the Delta region than has
12 been during the previous 175 years. How good is our
13 present data base? I would like to discuss the
14 available, and I mean published or available unpublished
15 information, for each of the major groups of wildlife -
16 fish, birds, mammals - as well as for some selected
17 species. When I speak of what we know, I am referring
18 only to this published or available information.

19 The Mackenzie Delta Area can
20 be divided into four general drainages: the Yukon
21 River Basin, which includes the Porcupine and Bell
22 Rivers; the Yukon North Slope which includes the Firth,
23 Babbage, and Blow Rivers; the Mackenzie River Basin,
24 which includes the Peel River and the modern Mackenzie
25 Delta; and the Eastern Coastal Drainage, east of the
26 Modern Mackenzie Delta, which includes the Miner,
27 Kugaluk, Anderson, and Horton Rivers. The majority
28 of the information available on fish in the Delta
29 region is from the first three of these drainages;
30 virtually nothing is known of the Eastern Coastal

A.M. Martell
In Chief

Drainage.

The general distributions of the 61 species of fish reported from the Delta Area have been reasonably well documented for freshwater species in the modern Mackenzie Delta and west. However, little is known of their distributions east of the modern Delta, and even less is known of their distribution in coastal waters.

A total of only about fifty known spawning sites and forty known nursery sites have been located in the region, primarily since 1971. When these locations are mapped it can be seen that they appear to occur in discrete areas, rather than being scattered throughout the entire region. Further, these discrete areas lie principally along the proposed pipeline corridors. Therefore the distribution of known spawning and nursery sites within the Delta region merely reflects where they have been looked for intensively, and it cannot be assumed, either that the most important have been found or that a stream crossing the pipeline route will not have an important site on it, outside of the corridor. Also, only about one-third of the species have recorded spawning sites, and only about one-quarter have recorded nursery areas.

Although some species of fish in the Delta region are relatively sedentary, others follow seasonal migrations which may be either fairly local or over long distances. There is relatively little information available on these movements, although we know that lake whitefish, broad whitefish, and

A.M. Martell
In Chief

1 inconnu, some are in coastal waters and make long upstream
2 migrations in the fall, perhaps as far as Fort Good
3 Hope. Seasonal spawning migrations have been recorded
4 for a few species of fish in parts of the region.
5 Seasonal movements have been documented only at a few
6 sites in the Delta Area. In this I mean continuous
7 records of the proportions of catch at specific sites:
8 Aklavik, Arctic Red River, Rat River, and then only for
9 one or two years. No information is available on
10 longterm fluctuations in the timing or magnitude of
11 seasonal movements or spawning runs.

12 Of the major fish species in
13 the Delta Area, good biological data are available only
14 for the Arctic char; the biology of most of the
15 other species is generally poorly known. Burbot, or
16 loche, and lake char - lake trout - are conspicuous
17 by the lack of information, even on their reproductive
18 patterns and movements, despite the importance of
19 these two species to Delta area residents.

20 Because of the lack of good
21 longterm, quantitative data on even the major fish
22 species in the Delta area, it is unlikely either that
23 any slight disturbance to their populations could be
24 detected, or that the exact cause of any major
25 disturbance could be assigned.

26 The general distribution of
27 the 118 species of birds reported breeding in the
28 Delta area is reasonably well known; however, the region
29 east of the modern Mackenzie Delta is generally poorly
30 known compared with the modern Delta and the area to

A.M. Martell
In Chief

1 the west. This is primarily due to recent research
2 associated with the proposed pipeline corridors.
3 Breeding bird surveys have been done in several areas
4 along these proposed corridors since 1971, but only in
5 a very few sites - only a very few sites have been
6 sampled for more than one year. Therefore, no information
7 is available on potential annual fluctuation, in
8 either the composition or density of breeding bird
9 populations. Without such data it is impossible to
10 determine whether any changes detected in these
11 communities at a future date are due to man-induced
12 disturbance or to normal - we can class something as
13 being normal - variations caused either by annual
14 differences in weather patterns, or fluctuations in
15 some of the species themselves.

16 Probably the two most important
17 groups of birds in the Delta area, to Delta area
18 residents, are ptarmigan and waterfowl. Very little
19 is known of the biology of any of the three species
20 of ptarmigan, or any of the 16 species of ducks
21 breeding in the region, but the situation is better for
22 the whistling swan and the four species of geese.

23 An aerial census of waterfowl
24 has been made in the Delta area each spring since 1948.
25 This is by the U.S. Fish & Wildlife Service, originally.
26 These surveys show the great variation in both the
27 composition and density of waterfowl between years due
28 to natural variations in weather patterns. The
29 greatest duck densities and the highest proportion
30 of dabbling ducks, primarily Pintail, Wigeon, and

A.M. Martell
In Chief

1 Mallard, was found around 1960, which coincides with a
2 period of drought on the prairies. In dry years,
3 waterfowl which normally nest in prairie ponds move
4 further north where conditions are always wet.

5 Without such a continuous
6 record of waterfowl populations, changes in numbers,
7 either could not be assigned to a cause or could be
8 misconstrued. Porsild reported that nesting Canada
9 Geese in the southern part of the modern Mackenzie
10 Delta decreased markedly in the period 1915 to 1935,
11 and attributed this decrease to the increase in human
12 activities in the region. Because of the lack of a
13 data base, Porsild could not either truly document the
14 decrease, or assign its cause with any accuracy. Cowan,
15 a biologist who visited the modern Mackenzie Delta in
16 1947, compared his waterfowl observations with those
17 of Porsild who was there in 1934. Cowan reported a
18 total decline in waterfowl populations of 91 to 97%,
19 with the decline in Wigeon and Pintail approaching
20 99%. Cowan expressed great concern over this disastrous
21 decline. However, the apparent decline was probably
22 due to the great numbers of prairie waterfowl present
23 in the Delta area during the dry years of the 1930's,
24 as compared to more normal densities when Cowan made
25 his observations in 1947. Because he did not have ^a good
26 data base, Cowan could not reach this conclusion.

27 These cases, I feel, emphasize
28 the need for a longterm data base for the assessment
29 of the effects of potential disturbance. The base must
30 be sensitive, however. The aerial surveys of waterfowl

A.M. Martell
In Chief

1 run since 1948 give us a base to detect changes of
2 relatively large magnitude, but the technique is
3 relatively insensitive and would not enable small scale
4 disturbances to be detected.

5 Largely through the efforts
6 of Dr. Tom Barry of the Canadian Wildlife Service, who
7 has worked in the Delta area for over fifteen years,
8 we have good information on the biology of whistling
9 swan and geese: Brant, snowgeese, white-fronted geese,
10 and Canada geese; in the Delta area. This information
11 is essential because the greatest density of whistling
12 swans in Canada is found along the coastal strip from
13 the west side of the modern Mackenzie Delta to the
14 east side of the Anderson River Delta, and because
15 over 15,000 snow geese, 3,00 Brant, and 6,000 white-
16 fronted geese breed in the Delta area. Barry has also
17 collected vital information on the location of critical
18 areas within the Delta region for migrating, nesting
19 and moulting of waterfowl.

20 Two major waterfowl migration
21 pathways in northwestern North America pass through
22 the Delta area; the coastal route around Alaska used
23 by Brant, Oldsquaw, and eiders; and the Mackenzie River
24 Valley, used by the remaining waterfowl species.
25 Because of these major migration routes, most of the
26 waterfowl which breed in the western Arctic pass
27 through the Delta area in spring and fall. Barry
28 reported that in late May and early June 1972, almost
29 200,000 geese, over 1,100,000 Oldsquaw, and almost
30 1,240,000 eiders passed Cape Dalhousie on migration.

A.M. Martell
In Chief

1 THE COMMISSIONER: Excuse me,
2 where is Cape Dalhousie?

3 A Right at the tip of the
4 Tuk Peninsula.

5 The need for a detailed base
6 line data is clear.

7 Barry's study on the
8 reproductive biology of geese in the Delta area have
9 shown the sensitivity of geese to disturbance during
10 the breeding season. Because of the short Arctic
11 summer, the schedule of goose nesting activities is
12 very tight. Once nesting can begin, there is only about
13 a ten day period during which all other nests are
14 initiated. Incubation begins after the last egg of the
15 clutch is laid and lasts 22 to 24 days, depending
16 on the species. Young geese grow rapidly and this
17 rapid growth is necessary if the young birds are to be
18 able to migrate south with their parents at the end
19 of the summer. Because of this tight schedule, birds
20 which are delayed in nesting due to adverse weather
21 conditions, may not nest at all, and birds which lose
22 their clutches through weather or predation cannot
23 re-nest successfully.

24 Adverse weather conditions may
25 affect waterfowl both directly and indirectly. Barry
26 estimated that 100,000 eiders died of starvation in the
27 eastern Beaufort Sea in the the spring of 1964. He
28 attributed this mortality to the severity of the
29 weather; low temperatures allowed pack ice to be
30 present most of the summer and many leads to be frozen

1 over until mid-July. The adverse weather in 1964 also
2 resulted in the loss in the Anderson River delta of
3 100% of the snow goose nests, 75% of the white-fronted
4 goose nests, and 50% of the Brant nests. Adverse
5 weather conditions resulted in virtually no
6 goose nesting success in the Delta region again in
7 1974. Fortunately, years as severe as 1964 and 1974
8 are uncommon but they do illustrate the great influence
9 of environmental conditions on northern-breeding
10 waterfowl. These cases also illustrate the need for
11 a good longterm data base in order to begin to understand
12 how disturbances by man might affect waterfowl
13 populations. Waterfowl populations are probably much
14 more sensitive to disturbance both in years of adverse
15 weather conditions because of the generally poor
16 physiological condition of the birds, and in subsequent
17 years, when their losses are being made up, than in a
18 good year after a series of good years.

19 The distribution of most of
20 the 42 species of mammals resident in the Delta area
21 is probably better known than those of fish and birds.
22 However, we have good information on the biology of
23 only a few of these species. The aquatic furbearers,
24 beaver and muskrat, have received the greatest amount
25 of attention, primarily through the work of Vern Hawley
26 and Ward Stevens of the Canadian Wildlife Service.
27 Beaver and muskrat habitat has been surveyed and
28 classified as to its potential for fur production, and
29 detailed studies have been done on both species in the
30 modern Mackenzie Delta. From this work we know that

A.M. Martell
In Chief

1 populations of both species fluctuated greatly over the
2 years but they do not fluctuate together. In the last
3 fifteen years beaver populations were highest between
4 1962 and 1965, and then declined, as mentioned
5 previously, probably due to a degradation of food
6 supplies, while muskrats were very high in 1962 and
7 again in 1968, and were markedly lower in the other
8 years. The cause of these fluctuations is not known
9 and their predictability is not possible.

10 The detailed studies on beaver
11 and muskrat have outlined the sequence of events in
12 the animals' annual cycles and therefore provides
13 some insight into the periods of the year when the
14 animals might be the most vulnerable to disturbance.

15 Extremely little is known of
16 the biology of the remaining fur bearers of the region,
17 despite their economic importance. Arctic fox habitat
18 has been mapped and some surveys of denning density
19 were run on the Yukon North Slope during one year. Den
20 site requirements of Arctic fox and red fox on Richards
21 Island have been examined briefly. Except for the
22 small amount of information, virtually nothing is known
23 of the biology of either Arctic fox or red fox in the
24 Delta area. Some studies have been made on marten and
25 mink but generally little is known. Virtually nothing
26 is known of the biology of wolf, wolverine, and lynx
27 in the Delta area.

28 As I pointed out earlier, when
29 I say "nothing is known" I am referring to published
30 information. It is impossible for a man to be a

A.M. Martell
In Chief

1 successful trapper and not know a great deal about the
2 habits of the animals he is trapping, and there are
3 many successful trappers in the Mackenzie Delta area.
4 The trapper must be aware of the habitat types used
5 by the animals for hunting and for shelter, and their
6 times of activity and movement. The trapper is also
7 very aware of the sensitivity of the animals to foreign
8 odours, which may be found in traps and trapping
9 equipment, and to the alteration to snow cover and
10 vegetation caused by trapping activities. This
11 knowledge is gained through many years of experience.
12 The trapper is sensitive to changes in animal numbers
13 and behaviour in the local areas he is familiar with.
14 Because he does not have sufficiently detailed information
15 on the animals' year long activities over a large area,
16 he cannot always make accurate interpretations of his
17 observations. And if I could digress a minute, here,
18 this is fairly clear because of the relatively rigid
19 schedule of yearly activities that a trapper is tied
20 to. In areas, for instance, where he might be
21 hunting Arctic fox or trapping Arctic fox on the coast
22 in the winter, at the time the same foxes are denning,
23 he's probably in an entirely different area, and
24 possibly occupied with other activities. He then has
25 no information on what conditions are present at the
26 time the Arctic foxes are actually denning, or on the
27 time the pups are being weaned.

28 (QUALIFICATIONS & EVIDENCE OF A.M. MARTELL
29 MARKED EXHIBIT 445)
30

1 virtually nothing is known of them.

2 Moose and Dall sheep habitat
3 has been mapped in the delta area, and the most
4 important areas for these species have been identified.
5 Except for this documentation of distribution,
6 virtually nothing is known of the biology of moose or
7 Dall sheep in the region.

8 Until very recently, little
9 was known of the biology of bowhead or beluga, in the
10 delta area. Information gathered ^{within} the last ten years,
11 and particularly within the last five years, has
12 greatly increased our knowledge of whale numbers and
13 movements in the eastern Beaufort Sea, and of
14 variations between years. However, the variation
15 in this information gathered, underlines the need for
16 continuing studies of a good data basis to be
17 established. Little information is ^{yet} available on the
18 basic biology of whales in the delta region.

19 Grizzly bear, polar bear and
20 seals are also of importance to the people of the delta
21 area. These animals have been receiving attention
22 within the last few years. Surveys are being run by
23 the Canadian Wildlife Service to determine the
24 distribution of polar bears and ring seal and bearded
25 seal along the coast of the delta area. More intensive
26 work is presently being done in the eastern Beaufort
27 Sea and Amundson Gulf. This data will have some
28 application to populations in the delta region.

29 Grizzly bear habitat has been
30 surveyed in the delta area, and some basic information

1 on their biology has been collected. Presently more
2 intensive studies of grizzly bear are being carried
3 out by the Canadian Wildlife Service and these should
4 produce a better data base, for the evaluation of
5 man-induced disturbance to the grizzly populations.

6 Within the last fifteen years,
7 there have been many cases of disturbance to wildlife
8 in the delta area. These have been due both to physical
9 alterations to wildlife habitat, such as gravel pits,
10 seismic lines, drilling sites, winter roads, and
11 artificial islands, and to the increased presence of
12 man and his machines; this latter case exemplified
13 both by the density of staging sites, seismic camps,
14 drilling rigs, and by the large amount of overland
15 travel by nodwells, and trucks in winter, boats in
16 summer, and airplanes and helicopters year-round.

17 Residents of the delta area
18 have reported that fish in the Eskimo Lakes and Crossley
19 Lakes, and muskrats and snowshoe hare in the modern
20 Mackenzie Delta have been affected by these disturbances.
21 However, very little research has been done, either
22 to determine the effects of these disturbances, or
23 to confirm or deny the observations of delta residents.

24 I have reviewed the historical
25 evidence of disturbance to the wildlife of the delta
26 area by resource extraction industries in the past.
27 We can be sure that present resource extraction based
28 in this delta area
28 industries are also causing disturbance to delta
29 wildlife. However, we do not know the magnitude of
30 this disturbance.

A.M. Martell
In Chief

1 Because of the historical, present and future
2 importance of wildlife to residents of the delta area,
3 it is essential that the resource be maintained. This
4 can be accomplished only through careful management of
5 the resource, to ensure firstly that the status of
6 any component of the delta fauna is not seriously
7 altered, and secondly that the resource be available
8 for continuing use by delta residents.

9 Throughout this presentation,
10 I have emphasized the necessity for a solid long-term
11 data base in order to detect and assess the effects
12 of man-induced disturbances to wildlife population.
13 I do not feel that this can be over-emphasized. The
14 onus of proof should not be on the party who suggests
15 that disturbance has occurred, for without such a data
16 base he will not be able to demonstrate cause, except
17 in the most obvious cases, which are often only ones
18 of very great disturbance.

19 The onus of proof should
20 rather rest on the party wishing to cause a predervation(?)
21 to demonstrate that wildlife populations will not be
22 affected, and I believe that this is only possible
23 with a solid long-term data base.

24 MR. BAYLY: Mr. Commissioner,
25 that completes the direct evidence of Dr. Martell,
26 and he is available for cross-examination at this
27 time.

28 MR. GOUDGE: May I suggest
29 that we break for coffee, sir?
30

A.M. Martell

Cross Exam by Goudge

1 THE COMMISSIONER: Fine

2 (PROCEEDINGS ADJOURNED FOR A FEW MINUTES)

3 (PROCEEDINGS RESUMED PURSUANT TO ADJOURNMENT)

4 THE COMMISSIONER: Well, Mr.
5 Carter, any question?

6 MR. CARTER: I don't have any
7 questions.

8 THE COMMISSIONER: Mr. Lutes?

9 MR. LUTES: No thank you,
10 Mr. Commissioner.

11 THE COMMISSIONER: Mr. Goudge?

12 MR. GOUDGE: Yes sir.

13
14 CROSS-EXAMINATION BY MR. GOUDGE:

15 Q Dr. Martell, you conclude
16 your evidence by speaking of onus of proof, and that
17 follows your general proposition, as I understand you,
18 that a longterm data base is absolutely essential.
19 That's your basic proposition.

20 A Yes.

21 Q That data base is
22 essential if one is to make any analysis of impact of
23 any kind?

24 A I'd like to refer, if I
25 could, to really intending it to be a little broader.
26 Now, we may be able to get away with a slight amount of
27 information, let's say we can detect a disturbance, but
28 what can we do about it? I would maintain that this
29 good data base, in other words one that would enable
30 us to make good management recommendations, is necessary

A.M. Matzell
Cross-Exam by Goudge

1 in order to first of all detect, it certainly will
2 do that; but it also will allow us a means of correction,
3 or modification to practices, which may be causing
4 a disturbance.

5 Q Could you give me an
6 example of that second consequence the adequate data
7 base?

8 A Let's take the case of
9 water fowl. That's probably, I think, the best one,
10 of geese nesting where it's been well enough and
11 carefully enough documented that, if observations are
12 made, let's say, in large losses of clutches in an
13 area, during a year when there apparently is no harsh
14 environmental conditions - there haven't been any
15 storm tides, or something - maybe, let's say there has
16 been heavy aircraft activity because it happens to be
17 on a flight route, this small colony, hypothetical
18 colony is on a flight route between a staging area and
19 a rig site, as an example. One may not at first of
20 all, without the base one may not have been able to
21 detect what was might have been able to detect what was
22 occurring, but wouldn't have known that this loss in
23 clutch, 20 or 30 per cent, was unusual.

24 With the base we can say, yes
25 it's unusual, and because we know the pattern is tight
26 enough on the birds, and because we know the incubation
27 time is important, we can start to look at it carefully,
28 and perhaps we'll see that the aircraft flight route
29 flight has been low enough to cause the birds to be
30 leaving the nests at a frequency great enough that

1 they're losing the clutches, due to lack of proper
2 incubation time. This can then be easily corrected by
3 altering the flight route, cancelling the flights,
4 raising the height or one thing or another.

5 Now, in the other sense, if
6 we had no information on the birds, except that they're
7 in the area, and we detect a slight loss, a bit of a
8 loss in clutches, we first of all may not be sure that
9 that's not normal. Even if we are, we may not be sure
10 why.

11 Q Let alone what to do about
12 it.

13 A Let alone what to do about
14 it.

15 Q Yes, I understand that.
16 In dealing with the onus of proof that you refer to
17 then, you're not suggesting I take it, that the onus
18 of proof is on the developer to do anything more than
19 suggest the impact. You're not suggesting that the
20 onus of developing the data base is the developer?

21 A No.

22 Q I take it you would see
23 that to be a job for government?

24 A Yes.

25 Q I wonder if you've given
26 any thought to dealing with the particular area of
27 concern that we have, and perhaps more particularly
28 the delta within the valley; whether given your views
29 of the inadequate data base, what kind of general
30 research program would be necessary to bring it up to

1 standard?

2 A I'm afraid I feel quite
3 incompetent really to comment on that, and that I'm
4 not really aware of the actual detail of the projects
5 presently ongoing, that have not been published. I
6 don't think it would be appropriate for me to make
7 such comment without this information.

8 Q I see. There's no doubt
9 that there are a number of ongoing studies which will
10 add to the baseline data in the area.

11 A Yes. I feel that it is
12 increasing, but I do feel that there's a need for a
13 strong government involvement, particularly in
14 relation to developing management programs, around the
15 various species, and the system as a whole, in order
16 to truly both assess, and do something about, or
17 correct, moderate any potential disturbances.

18 Q Yes. But there's no
19 doubt, I take it, in your mind that over the past five
20 or ten years in particular, there's been a substantial
21 addition to our baseline information, in the valley
22 and the delta, and to give government and industry
23 their due, they've participated in large measure in
24 that.

25 A That's right. But I
26 feel there still is -

27 Q Your view is there's still
28 a long way to go.

29 A Still a long way to go,
30 yes.

A.M. Martell
Cross-Exam by Goudge

1 If I could make a comment on
2 that, as well, I feel ^aas/personal opinion, that there's
3 a very great value to having, let's say, one researcher,
4 or several researchers, working in an area, be it even ^{if}
5 they're changing projects. If they're working on
6 species A for a few years, and then switch over to
7 species B, and maybe to C, there's an intangible value
8 that's very hard to pinpoint, that's gained through the
9 experience of this individual working in the area, and
10 preferably living in the area, continuously over a long
11 term.

12 He's able to make, I feel,
13 very good judgements on things that he may not
14 specifically have worked on, but he has been able to
15 carry out observations on, over a long period, and I'd
16 like to put this in contrast to a similar length study,
17 done by a dozen different people, none of whom have
18 spent more than one year in the same area; and I really
19 feel there's a significant difference in what one can
20 do in terms of management, with these two types of
21 programs.

22 Q So at least one of the
23 factors you would build into a program necessary to
24 build the baseline data bank to an adequate state,
25 would be just that; keep the same people around on a
26 variety of subjects.

27 A Preferably residents of
28 the area.

29 Q Do you have any views as
30 to how long, in general terms, it would take to get

A.M. Martell
CROSS-Exam by Goudge

1 this baseline data to a position where you feel it
2 would be adequate ?

3 A I'm inclined to comment
4 similar to Dr. Pimlott's testimony this morning, where
5 he said, well, we can have - there is a very long term,
6 but this is not always realistic in terms of the
7 planning that's necessary, so we should be looking at
8 shorter term programs around them, and I think perhaps
9 in some areas, I'm not familiar with all of the testi-
10 mony ^{been} that's presented, but I'm certainly at least in
11 some species, probably the testimony has come in, I
12 would anticipate, would enable some of these decisions
13 to be made with the data base gathered so far.

14 But I think it's important
15 that we look a little broader than perhaps has been
16 looked, in case there are specific links that we are
17 missing within the system as a whole, rather than just
18 concentrating on the glamour species.

19 Q Are you prepared to
20 comment on Dr. Pimlott's sort of outside time frame of
21 ten years for the development of this kind of data
22 bank that's satisfactory?

23 A I would think that a
24 great deal could be accomplished by a number of
25 individuals working in the area over a ten year
26 period continuously. I think within that time frame certainly
27 they should be able to develop good management programs,
28 for the most important species.

29 Q Well within that
30 time frame?

A.M. Martell
Cross-Exam by Goudge

1 A I would hope so, yes.

2 Q Five years?

3 A I think this is contingent
4 upon the fact, within five years they should ^{have} developed
5 to the point that given that they will be there the
6 remaining five years, while some information is needed,
7 then maybe yes. If they were to be replaced in five
8 years with somebody else that just had their reports to
9 refer to, perhaps not.

10 Q I take it you'd be
11 reluctant to see anything satisfactory develop within
12 a time|frame of much less than five years?

13 A Personally, I'd feel that
14 five years would be a minimal time.

15 Q Now sir, in dealing with -
16 on page 19 of your prepared evidence, certain of the
17 disturbance factors that have occurred in the delta in
18 the last fifteen years, you concentrate in large part
19 on alterations to the physical habitat. I take it you
20 acknowledge as well, the environmental impact of
21 increased access due to, and hunting consequent on that
22 for example, as a factor leading to impact.

23 A Yes, this would be
24 something that -

25 Q If you had to compare
26 those two general kinds of impact, alteration of habitat
27 versus increased access and accompanying increase in
28 hunting, which has been over the last ten or fifteen
29 years, of more damage?

30 A I would presume it was the

A.M. Martell
Cross-Exam by Goduge

1 physical, and those due to man's travel and activities;
2 in other words the non-hunting forms of disturbance.

3 Data on beluga hunting, for
4 instance, seems to indicate that there may not have been
5 any substantial difference in the average yearly kill
6 over perhaps the last twenty years.

7 Would you be prepared to
8 qualify that comparison? Is the physical four times,
9 five times as damaging?

10 A No. I'm afraid I can't.
11 Really all I can say that I am, in terms of this
12 testimony, is I'm a reviewer, I^{have} reviewed a great deal
13 of published information. I don't claim to be an
14 authority on this whole broad area. Rather, I've
15 reviewed the information, and due to the fact that
16 there aren't any other reviews of a similar nature
17 available, and I can comment only on what I've done.

18 Q I appreciate your
19 concern, Dr. Martell, and I'm happy to have you say
20 you'd rather not answer, if you don't feel qualified
21 to answer.

22 Let me ask you two or three
23 more questions. On page 6 of your prepared evidence,
24 if I can ask you to turn to that sir, you say at the
25 bottom that it is likely that, based on present day
26 information on the Porcupine caribou herd, that the
27 harvest had negligible effect on the herd as a whole.

28 Now dealing with that specific
29 reference, how do you come to that conclusion, what
30 was the information you used as a basis for that

A.M. Martell
Cross-Exam by Goudge

1 conclusion?

4 A Okay, one minute here.

5 It's based primarily on information gathered by Dr.
6 George Calef, and published. In looking at the caribou
7 herd reported in a 1974 publication, that the present
8 annual harvest was unlikely to exceed 4,000 animals,
9 or approximately 25% of the annual production; and he
10 concluded that this harvest has a negligible effect on
11 the herd.

12 Now, given the assumption that
13 an annual harvest of 4,000 animals on the present herd
14 size is negligible, then I concluded an average harvest
15 of 1,800 animals would also have been negligible, but
16 with the underlying assumption of course, that the
17 Porcupine herd was not significantly smaller at that
18 time of the whalers.

19 Q Obviously, if it was
20 smaller, hunting would have had an impact.

21 A It could have, and on the
22 herd as a whole, I try to emphasize there, and in
23 comparing the 1,800 and 4,000 animals the herd would
24 have^{had}/to have been half the size or less, in order to
25 have - the herd as a whole.

26 Q And while you think that's
27 unlikely, you simply have no data base available to
28 allow you to say that?

29 A Exactly.

30 Q Now let me ask you to
31 turn pages 14 and 15 of your prepared evidence, and as
32 I understand the general thrust of your evidence, and

A.M. Martell
Cross-Exam by Goudge

1 you tell me if I have it right, you say there in general
2 terms that some periods in the annual life cycle of
3 water fowl are very critical, and that adverse weather
4 conditions can affect water fowl population at those
5 times. Is that the general thrust of what you say in
6 those pages?

7 A Yes.

8 Q Would you agree that
9 man-induced disturbance in those times, even of a
10 normally minor nature, might have a very large impact,
11 particularly if it/^{is}imposed during those critical periods?

12 A Yes. It's quite likely
13 that disturbance of any nature, to the regular routine
14 of activities of the birds, would be damaging to their
15 annual production.

16 Q And I take it from that,
17 the conclusion is that during those times, there'd be
18 the most stringent control of activities?

19 A Yes.

20 Q So that what we may see if,
21 given the importance of time as an element, is controls
22 which have to vary in stringency according to the time
23 at which they apply.

24 A Exactly, and in the case
25 of water fowl, it's one of the few cases we can pinpoint
26 these are exact periods when it is most critical.

27 Q Would you assume though,
28 that if base line data research were done for other
29 species, that the same kinds of hyper-sensitive times
30 might show up?

A.M. Martell
Cross-Exam by Goudge

1 A Certainly for some of the
2 species, and probably there are certain critical periods
3 of the year for most of the species.

4 Q So as a dimension of the
5 management problem, time has to be a vital element?

6 A Right. It has to be year
7 round research involved.

8 Q But I'm speaking of what
9 one does in imposing constraints on activity, perhaps
10 I should call it the regulation problem. Time is a vital
11 dimension to efficient regulation.

12 A Yes.

13 Q Now finally, Dr. Martell,
14 as I understand you, you conclude from your research
15 and evaluation of past disturbance, that it is certainly
16 probable, perhaps very probable, that the anticipated
17 increase in activity and human population, following
18 these proposals that we're dealing with, would greatly
19 increase the disturbance to wildlife. In general terms,
20 do you have any doubt about that?

21 A I have no doubt.

22 Q I take it, the next step
23 as far as you're concerned, is that that will prove
24 detrimental, increased disturbance will prove detrimental
25 to wildlife populations in many instances.

26 A That's the question.
27 Disturbance is a very general term, and certainly we
28 can't have any activity by man without creating some
29 disturbance. The question is, is the disturbance, will
30 the disturbance, the increased disturbance, affect the

A.M. Martell
Cross-Exam by Goudge

1 populations significantly?

2 Q There's no doubt though,
3 that, I take it, that some alteration in the intensity
4 of management efforts will be required, if the problem
5 is to be coped with.

6 A Yes.

7 Q As far as you're concerned,
8 are the management agencies that exist at present to
9 deal with management of wildlife in the valley and the
10 delta, satisfactorily^{equipped} to handle this increased
11 problem, at present?

12 A I personally don't feel
13 they are. I feel that increased funding must be made
14 available, and staff perhaps as well, to the people who
15 are attempting to manage the populations now, in order
16 to cope with the increasing demands.

17 Q There's no doubt, I suggest
18 to you, that both manpower and funds will have to be
19 increased.

20 A That's my contention, yes.

21 MR. GOUDGE: I think, sir,
22 those are all the questions I have of Dr. Martell.

23 MR. BAYLY: I have no
24 re-examination, sir.

25 THE COMMISSIONER: Dr. Martell,
26 you said that in a period of approximately seven years,
27 at the turn of the century, 1,500 bowhead whales were
28 taken. Do you have any notion at all of the size of
29 the herd, that is the number of bowhead whales, that
30 were to be found there before the whalers came?

A.M. Martell
Cross-Exam by Commissioner

1 A The only conclusion I can
2 reach is that was probably a very good estimate also,
3 of the population at that time.

4 Q I see.

5 A Now, this is the population
6 using the eastern Beaufort Sea, not the entire bowhead
7 stock, of which it's a part.

8 Q You mean - well, what is
9 the entire bowhead stock, of which it's a part?

10 A It's what's referred to
11 as Bering Chukchi stock, winters in the Bering Sea,
12 moves north the largest part into the Chukchi Sea in
13 summer, and one component swings to the east and into
14 the eastern Beaufort Sea.

15 Q Also I was going to ask
16 you, you kind of caught us at a bad time, being the
17 last witness after three weeks of formal hearings -
18 you were talking about the presence of the bluenose
19 herds, that is that its range used to extend into the
20 delta, and it has withdrawn, it appears now. I think
21 this evidence came out at Yellowknife last month. It
22 appears now to be moving into the delta again.

23 A Yes. The material I had
24 available to me indicated that it had been increasing;
25 it designated as I did in the testimony the possible
26 presence of this group of intergrades, which I understand
27 from recent conversations I've had, but not document
28 published material, that this now may be engulfed by
29 part of the bluenose herd, or may have been part of the
30 herd, or the whole interfacing group of intergrades.

A.M. Martell
Cross-Exam by Commissioner

1 Q Yes. Now, just looking
2 at the map of the delta, can you tell me where that
3 is?

4 A The group of intergrades?

5 Q Would you mind just
6 showing me?

7 A In general, the
8 information I had available showed the porcupine herd
9 staying primarily to here, the barren ground caribou
10 probably showing up right into the delta islands, here,
11 and Ellis Island even, as well as right up the Tuk
12 peninsula originally. Presently, from the information
13 I had, it only came into this area, and this group of
14 intergrades is probably in this area, wintering in this
15 area, and in the summer to south of the lakes as
16 opposed to the reindeer herd which at least in recent
17 times, well within the last five to ten years anyway,
18 has summered on the Tuk peninsula and then wintered
19 either in this area, moving up to here to Taka,
20 or most recently in the Prise Lake area.

21 THE COMMISSIONER: Right.

22 MR. BAYLY: Dr. Martell, could
23 you identify those areas by name for the record,
24 because all we will have is "this area" and "that area."

25 DR. MARTELL: The Porcupine
26 herd I indicated the entire range west of the modern
27 Mackenzie delta. The barren ground caribou, prior to
28 1900, in the outer islands of the modern Mackenzie
29 delta, and everywhere from the Caribou Hills and down
30 into Caribou Lake, Travaillant Lake and east, at least

A.M. Martell
Cross-Exam by Goudge

1 at some seasons of the year; and presently, I indicated
2 from the information I had, it was primarily west of
3 the Kugaluk River, most likely based on some discussions
4 I've had more recently, it has actually moved closer to
5 Sitidge Lake and even into the Travaillant Lake area,
6 and this group^{of} possible intergrades probably summered
7 in the Urquart Lake area, and wintered in the
8 Travaillant Lake area. Then I indicated the modern
9 reindeer herd, or the European reindeer^{herd} in the area,
10 within the last five years at least, is summering on
11 the Tuk peninsula, wintering east, or excuse me, west
12 and north of Sitidge Lake, moving into Old Man Lake
13 to calve, and most recently wintering in the Parsons
14 Lake area.

15 MR. GOUDGE: Dr. Martell, in
16 terms of the bowheads, I'm correct, am I not, in
17 understanding that while they're not extinct, there
18 remain only about one hundred.

19 A This is the best available
20 guess that I've seen published.

21 Q And they, as you say,
22 winter in the east, but they do appear.

23 A Now this is the group
24 in the eastern Beaufort Sea, yes.

25 Q And they do come over as
26 far as Tuk, for instance, and beyond?

27 A Right, up past Cape
28 Bathurst area, north of that area, perhaps into Franklin
29 Bay.

30 Q Yes. And they're an

A.M. Martell
Cross-Exam by Goudge

1 endangered species, as I understand it?

2 A I don't feel qualified
3 to comment on that. I'm sure you'll be receiving
4 testimony in the next few weeks from somebody who's
5 able to.

6 MR. GOUDGE: Thanks, sir.

7 THE COMMISSIONER: When you
8 were studying the extent of the data that exists, with
9 relation to fish in the Mackenzie Delta, giving the
10 delta its larger definition that you have, did you
11 examine the testimony that Mr. Steigenberger gave
12 before the Inquiry in November or December?

13 A I finished my work on this
14 project last June, so I've been unable to examine
15 virtually any materials since last June.

16 Q You might - well, I leave
17 this up to Mr. Bayly, really, but it may be the work
18 of Steigenberger and Stein, and the other two people
19 from the fisheries who gave evidence with them, it
20 was already well known in one form or another in June
21 when you put together your presentation, but it strikes
22 me that perhaps not, because Mr. Steigenberger had done
23 an enormous amount of work on the north coast of the
24 Yukon, extending into what you call the delta.

25 Well at any rate, you might -
26 I'm sure that those volumes of evidence are easily
27 available to you - and you might just take a look at
28 their evidence, and just send a note in ^{through} Mr. Bayly,
29 if it alters your views in any way. I think that their
30 views essentially appear to confirm your own, but you

1 might want to add something when you examine their
2 testimony. And Dr. McCart as well. It kind of goes
3 on, with the lawyers cross-examining them all, but,
4 since you've reviewed the literature, your comments
5 would be appreciated.

6 A I'm certain, and I was
7 very concious of this all the time I was doing the
8 study, that I was constantly rewriting sections; because
9 I would have something written and suddenly a few more
10 reports would come out.

11 Q I know, I know the
12 feeling.

13 A So, it's a never-ending
14 sort of battle, and this increase in information within
15 the last five years is just increasing, it's going up
16 at a very rapid rate.

17 MR. BAYLY: We'll show those
18 to Dr. Martell, sir, and we'll be producing Stein in the
19 flesh again

20 THE COMMISSIONER: Oh you will,
21 eh?

22 MR. BAYLY: You may want to
23 address some of those questions to him as well.

24 THE COMMISSIONER: Mr. Stein
25 worked in the valley, Steigenberger on the Yukon coast.

26 MR. BAYLY: That's correct, sir.

27 THE COMMISSIONER: Okay, well
28 thank you very much, Dr. Martell. We appreciate your
29 very comprehensive review of the impact of man on the
30 life of the delta, and your suggestions regarding the

1 present state of knowledge. So, thank you again.

2 WITNESS MARTELL: Thank you.

3 (WITNESS ASIDE)

4 THE COMMISSIONER: And we'll
5 adjourn the inquiry --

6 MR. GOUDGE: Sir, before we
7 do that, just briefly so we'll all be clear, list the
8 batting order for when we come back in February. As I
9 understand it, Mr. Bayly has a list of the material that
10 he proposes to present to you, sir.

11 THE COMMISSIONER: Yes, excuse
12 me, just so there's no misunderstanding, the Inquiry
13 is meeting again tonight at 8:00/^{o'clock}in this hall to hear
14 the people from Inuvik who wish to speak and all of you
15 are invited to return here at 8:00/^{o'clock}tonight, and those
16 of you who live here and wish to say anything about
17 these matters may do so at that time, and I'll be pleased
18 to hear from you.

19 The formal hearings are
20 adjourned until a week Tuesday, at 10:00 A.M., and at
21 that time we will carry on with a two-week session of
22 hearings that will run right through to and including
23 Saturday, the first week resuming the following Monday
24 at 9:30, and running through until the following Friday.
25 We'll keep the same hours we've been keeping during this
26 session.

27 Now, Mr. Bayly will give us
28 the batting order so far as he's concerned?

29 MR. GOUDGE: Yes sir.

30 MR. BAYLY: Sir, I have seven

1 panels left in this portion of the evidence that we've
2 called the delta phase, for want of a better name, and
3 what is left is a panel on the Beaufort Sea biology,
4 containing approximately six people; a panel on the
5 physical nature of the delta and Beaufort Sea, containing
6 two people; Dr. Millen reviewing the Beaufort study,
7 and in particular an offshore blowout scenario that
8 was developed to look at the possible contingency plans
9 available, and that's just a single person panel; a
10 panel on exploration to date, of one person, and that
11 is seismic exploration to date, on and offshore; a
12 panel on some effects of exploration to date consisting
13 of fisheries people, two people; a contingency planning
14 panel of three people; and a community information
15 program panel of as many as five people.

16 Now that doesn't necessarily
17 mean that in all cases there will be a presentation
18 from each person. Some of this evidence has been
19 distributed; I anticipate we will have at least the
20 evidence of Messrs. Sterling and Grainger distributed
21 prior to people's leaving, if they're leaving tonight,
22 and perhaps one or two more pieces before tomorrow if
23 people are still here. We'll have to make arrangements
24 for the rest to be distributed by airfreight or by
25 whatever means, as soon as possible.

26 I would anticipate that with
27 the amount of cross-examination there has been so far,
28 that that may be able to be completed in that first
29 week of formal hearings, in the next segment.

30 THE COMMISSIONER: Yes. Well,

1 Mr. Carter, Mr. Marshall and you should, bearing that
2 in mind, be standing by ready to call your cross delta
3 evidence.

4 MR. GOUDGE: I was going to
5 suggest that, sir. The only other item that will be
6 added to our plate in the next two weeks, is, well
7 really two things that will be added; we will be
8 expediting the attendance of certain government witnesses
9 who will describe to you in general terms the regional
10 planning process that is proposed for the delta region,
11 we will also be expediting the attendance of certain
12 government witnesses who will provide you with a
13 general and accumulative environmental impact evidence,
14 as they have it, of the gathering lines and gas plants
15 on the delta.

16 Those witnesses will not be
17 our witnesses in the strict sense, but they will be here
18 and making presentations to you on those subjects, sir.

19 After that, I would anticipate
20 that we would be able, in the second week, to get into
21 the cross-delta application evidence of the applicant,
22 Canadian Arctic Gas.

23 And the one other comment I
24 would make sir, is that because of timetable difficulties,
25 obviously we may require some slight adjustments and
26 I know counsel will co-operate in filling any gaps that
27 may arise through necessities of transportation.

28 THE COMMISSIONER: Right, so
29 that will --

30 MR. BAYLY: Just on the batting

1 order sir, I am not quite clear when these witnesses
2 that the Commission counsel is expediting will arrive
3 and I would hope to have some word on that from them,
4 if not today, as soon as possible.

5 MR. GOUDGE: Yes, I'll under-
6 take to advise Mr. Bayly as soon as I know; I simply
7 can't tell right now.

8 MR. LUTES: Mr. Commissioner,
9 with respect to the two weeks which you are going to
10 sit, when you said you were going to sit through
11 Saturday, did you mean the Saturday after the end of
12 the first week?

13 THE COMMISSIONER: Yes.

14 MR. LUTES: And you intend to
15 adjourn on the Friday of the following week?

16 THE COMMISSIONER: Yes, that's
17 just as we have done this session. If we sit right
18 through to Saturday, then no one is tempted to leave
19 for Calgary for the weekend, and --

20 MR. GOUDGE: No one is able to
21 leave for Calgary sir.

22 THE COMMISSIONER: So, the
23 formal hearings stand adjourned then until a week
24 Tuesday at 10:00 in the morning, and the Inquiry is
25 adjourned until 8:00 o'clock tonight.

APPEARANCES:

Mr. Ian G. Scott, Q.C.,
Mr. Stephen T. Goudge,
Mr. Alick Ryder and
Mr. Ian Roland for Mackenzie Valley Pipeline
Inquiry;

Mr. Pierre Genest, Q.C.,
Mr. Jack Marshall, and
Mr. Darryl Carter for Canadian Arctic Gas
Pipeline Limited;
Mr. Reginald Gibbs, Q.C.,
Mr. Alan Hollingworth &
Mr. John W. Lutes, for Foothills Pipe Lines Ltd.;

Mr. Russell Anthony &
Pro. Alastair Lucas for Canadian Arctic Resources
Mr. Garth Evans Committee;

Mr. Glen W. Bell and
Mr. Gerry Sutton, for Northwest Territories
Indian Brotherhood, and
Metis Association of the
Northwest Territories;

Mr. John Bayly
or
Miss Leslie Lane for Inuit Tapirisat of Canada,
and The Committee for
Original Peoples Entitle-
ment;

Mr. Ron Veale and
Mr. Allen Lueck for The Council for the Yukon
Indians;

Mr. Carson H. Templeton, for Environment Protection
Board;

Mr. David Reesor for Northwest Territories
Association of Municipal-
ities;

Mr. Murray Sigler for Northwest Territories
Chamber of Commerce.

Mr. John Ballem, Q.C., for Producer Companys;

February 10, 1976

(PROCEEDINGS RESUMED PURSUANT TO ADJOURNMENT)

MR. GOUDGE: Perhaps I could put on the record four reports that have been received by our office in Yellowknife and which are in addition to those Mr. Scott put on the record the last time we were here. They're preliminary drafts of reports from the Beaufort Sea Environmental Program. We have copies available for the participants to consult if they wish, here in Inuvik.

The first is a report dealing with "Near Bottom Currents and Offshore Tides" by Huggett et al.. That's H-U-G-G-E-T-T. The second deals with "Hydrodynamics of an Oil Well Blowout" by Topham, t-o-p-h-a-m-. The third deals with "Oil, Ice and Climate in the Beaufort Sea" by Walker and the fourth deals with "Movement and Deformation of Land-Fast Ice in the Southern Beaufort Sea" by Cooper. Those reports we have available for inspection.

MR. BAYLY: Mr. Commissioner, while we are housekeeping, I have four reports in the possession of COPE and I'll be sending out a letter to the participants, but I'll announce the names of those reports for the record in case the letter doesn't get out during the next week. The first one is by Dr. Peter Usher, "Evaluating Country Food in the Northern Native Economy".

The second is by N. Simmons

Percy, Grainger, Barry,
Sergeant, Smith, Stein
In Chief

1 and T. Barry, "Oil Exploration and the Banks Landers".
2 The third one is "The Application for Drilling Authority",
3 volume one, Dome, Gulf and others. Tingmiaik, T-i-n-g-m-
4 i-a-i-k, K-91 and Dome Hunt Kopanoar, K-o-p-a-n-o-a-r,
5 D-14, volume 2; "Oil Spill Contingency Plan", Dome
6 Petroleum Limited, and the fourth one is comments
7 on the draft of Beaufort Sea project summary docu-
8 ment entitled "Offshore Drilling for Oil in the Beaufort
9 Sea", a preliminary environmental assessment, November
10 27, 1975.

11 Mr. Commissioner, if I could
12 introduce this panel to you and then ask the members
13 individually if they'd go over their qualifications.
14 On the extreme left and working to the -- to your right
15 sir, we have Dr. Percy, Dr. Grainger, Dr. Barry, Dr.
16 Sergeant, Dr. Smith and Mr. Stein.

17 JONATHAN ARTHUR PERCY, sworn
18 E. H. GRAINGER, sworn
19 THOMAS W. BARRY, sworn
20 D. F. SERGEANT, sworn
21 THOMAS G. SMITH, sworn
22 JEFFREY N. STEIN, resumed:

23 DIRECT EXAMINATION BY MR. BAYLY:

24 Q I wonder if we could
25 start with you, Dr. Percy, if you'd be -- they -- the
26 witnesses have been sworn, sir -- if you'd be good
27 enough to go over your curriculum vitae for the
28 record.

29 WITNESS PERCY: Yes, I received
30 by Bachelor of Science Degree from Carleton University
in 1964; my Masters Degree from Memorial University in
Newfoundland in 1968, and a PhD Degree from Memorial

Percy, Grainger, Barry,
Sergeant, Smith, Stein
In Chief

1 University of Newfoundland in 1971, specializing
2 in Marine Biology and Physiology of Marine Invertebrate

3 From 1971 - 72, I was a post-
4 doctoral Research Associate at the University of
5 Alaska, Institute of Arctic Biology, specializing in
6 zoophysiology and at that time I participated in
7 the cruise of the research vessel "R/V Alpha Helix" from the
8 Scripps Institute of Oceanography into the Bering Sea.

9 Since 1972, I've been a
10 research scientist in marine physiology biological oceanography
11 at the Arctic Biological Station in Ste. Anne de Bellevue,
12 Quebec where I'm specializing in environmental physiology
13 of arctic marine invertebrates.

14 Q Thank you sir. Dr.
15 Grainger, could go over your qualifications for the
16 record, please?

17 WITNESS GRAINGER: I attended
18 elementary and high school in Moncton, New Brunswick.
19 I went Mount Allison University in Sackville, New
20 Brunswick for a B.A. in 1947, then to McGill in Montreal
21 for an MSc in 1949 and a PhD in 1953.

22 I am employed by the Fisheries
23 and Marine Service of Environment Canada and have
24 been for -- since 1953, during which time I've worked
25 primarily in the Arctic. I am in charge of the
26 biological oceanographic group at the Arctic Biological
27 Station and at the moment, I'm serving as Acting
28 Director of the Arctic Biological Station in Ste.
29 Anne de Bellevue.

30 Q Thank you sir. Dr. Barry?

Percy, Grainger, Barry,
Sergeant, Smith, Stein
In Chief

1
2 WITNESS BARRY: I attended
3 the Rochester, New York school system. After release
4 from the U.S. Navy, I received a Bachelors Degree from
5 the University of Rochester and then a law degree from
6 Syracuse University. After a spell as working for
7 General Motors in Labor Relations and Industrial
8 Relations, I guess I saw the light and returned to
9 university, started all over again at Cornell University,
10 where I got a Master of Science Degree, majoring in
11 Wildlife Management and Animal Physiology, and later
12 a PhD in Zoology at the University of Alberta.

13 I worked for the Canadian
14 Wildlife Service for nineteen years. Most of my
15 work has been in the Arctic; three years at Southhampton
16 Island and around the eastern Arctic and then since
17 1957, I've worked out of this western area, out of
18 Inuvik. I've lived in Inuvik for seven years.

19 During this time, some of
20 the relative experience to this Inquiry, I did all
21 the surveys and followed the descriptions all the
22 way through to the Order-in-Council establishing bird
23 sanctuaries across the western Arctic -- in particular,
24 the Kendall Island Bird Sanctuary right here in the
25 delta; Anderson River Delta Migratory Bird Sanctuary,
26 two bird sanctuaries on Banks Island, one at Cape
27 Perry and one at Queen Maud Gulf over much further
28 east.

29 I've participated in various
30 studies in this area. One was mentioned, the Banks
Island study, which I guess is now released, I had them

Percy, Grainger, Barry,
Sergeant, Smith, Stein
In Chief

1 for the Minister of Indian and Northern Affairs. I
2 participated in the study of cultural and economic
3 values of wildlife on Bathurst Peninsula for the people
4 of Tuk. I don't know the status of that, whether it's
5 still in Indian Affairs hands or not.

6 I operated a boat along the
7 Arctic Coast for ten years -- twin engine -- twin diesel
8 boat, so I've become fairly familiar with the coast
9 between Herschel Island and Bathurst Peninsula. I
10 participated in a study with a local person from Sachs
11 Harbour a number of years ago on the wildlife values
12 and use of various species of wildlife by native
13 peoples of the Mackenzie Delta region, excluding Inuvik --
14 most of the out-settlements.

15 I'm now stationed in Edmonton,
16 have been since 1970.

17 Q Thank you Dr. Barry. Dr.
18 Sergeant, could you go over your curriculum vitae for
19 the Inquiry, please?

20 WITNESS SERGEANT: I studied
21 zoology, botany and geology at Cambridge University,
22 U.K., taking an honors degree in zoology in 1948, and
23 taking my PhD. in 1953 in the subject of experimental
24 ecology of fishes. Since 1951, I have been with the
25 Fisheries Research Board of Canada, now part of the
26 Fisheries and Marine Service of Environment Canada,
27 first stationed at St. John's Newfoundland Biological
28 Station and later at the Arctic unit in Montreal which
29 in 1965 became the Arctic Biological Station at Ste.
30 Anne de Bellevue, Quebec.

Percy, Grainger, Barry,
Sergeant, Smith, Stein
In Chief

1 I have studies the biology of
2 the great whales on the East Coast of Canada, the harp
3 and hooded seals of the East Coast and the arctic
4 whales, white whale, narwhal and bowhead and their
5 management.

6 I visited the delta in July-
7 August, 1961, visiting Inuvik, Aklavik, Shingle Point
8 and Kendall Island in travelling by aircraft and river-
9 boat.

10 Mr. Hoek, who is a coauthor,
11 with my submission, having carried out many of the
12 later observations, is the technician working with
13 me who joined the Arctic Biological Station in 1966,
14 coming from MacDonald College, Quebec, where he worked
15 in agriculture and entomology. He has visited the
16 delta in 1968, 1969, 1972 and subsequently every summer
17 and several autumns up to 1975 inclusive, carrying out
18 surveys of whales and studies of native people's
19 whaling. He is presently studying French.

20 Q Dr. Smith, could you go
21 over your qualification for the Inquiry, please?

22 WITNESS SMITH: I received
23 my Bachelors Degree from Bishop's University in 1965,
24 an MSc. Degree in limnology from this same university
25 in 1968. I then attended McGill University where I
26 received a PhD Degree in Marine Sciences, setting the
27 population dynamics of ring seals in the Home Bay
28 area of eastern Baffin Island. I received the degree in
29 1971.

30 I've been working for the

Percy, Grainger, Barry
Sergeant, Smith, Stein
In Chief

1 Arctic Biological Station at Ste. Anne de Bellevue
2 since 1968 and I've been employed there as a full-time
3 staff member since 1971.

4 I've done population dynamics
5 studies of a ring seal out of Pangnirtung and Broughton
6 Island on the east coast of Baffin Island and then
7 moved the same type of studies over to Holman Island
8 in 1971. We've been carrying out continuing studies
9 in the Anderson Gulf area. Since that time, studies
10 have branched out into other aspects considering
11 predation of ring seals by arctic foxes and polar bears;
12 and have developed into a -- into ecophysiological
13 studies which we've been carrying out since 1972 on
14 captive ring seals.

15 Q Thank you sir. Mr. Stein
16 has been a witness before, sir, and unless you wish it
17 I would not have him read his--

18 THE COMMISSIONER: I remember
19 Mr. Stein well and I remember his testimony well.

20 MR. BAYLY:

21 Q All right. I wonder if
22 we could begin with the evidence then of Dr. Percy, sir,
23 and there are two portions to this. He'd be commencing
24 with the one entitled "The Nature of the Threat of Oil
25 Pollution to Marine Life".

26 WITNESS PERCY: This first
27 section of the evidence is primarily a simplistic
28 summary of some of the problems people have in working
29 with oil in the marine environment and looking at oil
30 impacts on marine organisms, to give you some idea of
the reasons for the uncertainty that will become evident

Percy, Grainger, Barry,
Sergeant, Smith, Stein
In Chief

1 in the second presentation a bit later.

2 The potential for a major
3 oil pollution incident in the arctic has increased
4 quite dramatically over the past several years and
5 has led Dunbar to suggest that oil pollution is now the
6 most serious and immediate threat facing the arctic
7 ecosystem.

8 THE COMMISSIONER: Excuse me.
9 Dunbar's name has come up before. Who is Dunbar? I
10 know this must seem --

11 A Well, he might be con-
12 sidered the dean of arctic biology in Canada. He is
13 presently at McGill University. I think probably Dr.
14 Grainger would have more information on him, as Ted
15 Grainger is a student of Max Dunbar's.

16 THE COMMISSIONER: No, that's
17 fine for now. I -- forgive me, I had read, I think,
18 some things he wrote, but he hasn't been a witness and
19 that --

20 A No, I don't think so.

21 THE COMMISSIONER: -- That's
22 our loss, to this point.

23 A This is particularly true
24 for the arctic marine ecosystem now that emphasis is
25 rapidly shifting to offshore drilling in the coastal
26 waters of the Beaufort Sea. The technological
27 feasibility and potential hazards of such an under-
28 taking are subjects of continuing debate and speculation,
29 as you all well know. Particular concern has been
30 been expressed for climatological and ecological con-

Percy, Grainger, Barry,
Sergeant, Smith, Stein
In Chief

1 sequences of major submarine well blow-outs. The
2 glaring inadequacy of our present understanding of
3 both short and long-term effects of such accidents
4 has been brought into sharp focus by this continuing
5 debate. Our ecological ignorance has made it difficult
6 to realistically sustain or even to convincingly refute
7 the many highly speculative predictions of widespread
8 environmental disaster, and I'm sure many of you have
9 seen a lot of these predictions that have been sort of
10 off-the-cuff predictions of what would happen if there
11 was an oil spill.

12
13 As Dunbar again, so aptly
14 puts it, "we have been caught in a state of scientific
15 near nudity in the particular respect in which we now
16 so urgently need protective covering; namely knowledge
17 of what the proposed developments will do to the environ-
18 ment in precise terms, and knowledge of what should be
19 done to conserve and protect."

20 As you can well imagine, near
21 nuditiy in the arctic is not a particularly comfortable
22 state, be it scientific near nudity or actual near
23 nudity.

24 THE COMMISSIONER: Well, Dr.
25 Percy, Dunbar said that in 1971, I gather from your
26 statement.

27 A Right.

28 Q Does he still subscribe
29 to that point of view? Is it one that he would re-
30 gard as applicable today?

Percy, Grainger, Barry
Sergeant, Smith, Stein
In Chief

1
2 A In general, I would think,
3 yes, discussssions with him, I think he'd -- there have
4 been advances, certainly, as I'll make -- as I'll point
5 out a bit later on, but I think the general statement
6 still holds a lot of water.

7 This general uncertainty is
8 unquestionably compounded by the fact that little
9 reliable information is available about even basic
10 ecology and physiology of the overwhelming majority
11 of arctic marine species. This creates problems in the
12 effective conduct and proper interpretation of experi-
13 mental studies on interactions between crude oil and
14 arctic organisms. Furthermore, it makes it especially
15 difficult to assess the applicability, in the artic
16 context, of generalizations about oil ecosystem inter-
17 actions derived from numerous studies conducted in
18 temperate and tropical marine areas.

19 Even in temperate waters where
20 intensive research has provided a solid information
21 base, it is still impossible to predict, with any
22 degree of confidence, the precise ecological effects of
23 an anticipated oil spill. Even after an oil spill has
24 occurred it has proven very difficult to assess the
25 overall detailed environmental impact. Given the dearth of
26 information about arctic marine ecosystems, attempts
27 at detailed impact prediction at present can be considered
28 as exercises in futility.

29 Ecological concern has thus far
30 been centered primarily upon those components of the

Percy, Grainger, Barry,
Sergeant, Smith, Stein
In Chief

1 ecosystem that are of direct present or potential
2 economic importance to northern residents, particularly
3 marine mammals and water fowl. Although one should
4 not underestimate the importance of gaining as complete
5 an understanding as possible of direct effects of oil on
6 these economically important animals, it would be
7 particularly short-sighted and potentially rather
8 dangerous, to confine our attention to just these species.
9 They do not and cannot exist in a vacuum but are part
10 of a complex ecological web characterized by a multitude
11 of vital interdependencies, as you will see a bit later
12 on, as these presentations emerge.

13
14 Thus far, little attention has
15 been paid to those "low profile" organisms of little
16 direct economic consequence that nevertheless, form a
17 critical part of the ecological web upon which higher
18 forms are dependent.

19 It's generally conceded that
20 recovery from a severe ecological disturbance, such
21 as a major spill, would be a lengthy process in the
22 Arctic. This is a consequence of the slow growth,
23 extended life cycles and longer reproductive periodi-
24 city of Arctic animals as well as the slow dispersion
25 and degradation of oil at the lower temperatures.
26 However, it is still not quite clear just how susceptible
27 various components of the Arctic marine ecosystem are
28 to damage by oil pollution in the first place.

29 In view of the great complexity
30 of potential interactions between oil and animal communi-
ties, it would be manifestly impossible in a study of

Percy, Grainger, Barry,
Sergeant, Smith, Stein
In Chief

1 limited duration such as I will report on in the
2 second portion, to explore then a few of the -- to explore
3 more than the few -- than a few of the many aspects of
4 the problem.

5
6 Unlike many other pollutants,
7 crude oil is relatively insoluble in seawater and
8 creates the first of the problems. As a consequence,
9 spilled oil does not spread uniformly through the
10 environment but tends rather to concentrate in specific
11 areas of the environment in a variety of different forms.
12 Marine organisms -- marine organisms may thus encounter
13 varying concentrations and forms of oil, depending upon
14 their habitat and circumstance. The habitats I'll
15 specifically be mentioning a bit later on are the inter-
16 tidal, the sub-ice, the water-column habitat and the
17 bottom habitat and each of these habitats have specific
18 species associated with them and each of these habitats
19 is subject to oil in different forms and in different
20 quantities and so the animals living in them are going
21 to experience different effects of the crude oil.

22 Interaction of animals with
23 oil in any of the above forms in habitats may result
24 in three distinct levels of effects. The threshold
25 concentrations for each of these levels differ quite
26 considerably. Generally, we can distinguish the --
27 first, the short-term lethal effects in which the animals
28 succumb quite rapidly and usually fairly high oil concen-
29 trations are involved in this type of damage, concen-
30 trations in the high parts per million and low parts
per thousand range are involved.

Percy, Grainger, Barry
Sergeant, Smith, Stein
In Chief

Secondly, we have sub-lethal physiological effects which don't result in rapid death of the organism but involve major modifications in a variety of physiological processes that may prove lethal in the long term. Such effects generally become apparent at oil concentrations much lower than the lethal effects and we're talking about here in the high parts per billion and low parts per million range, and these are just generalized ranges at the moment.

Thirdly, we have a class of effects that are only just now even in temperate waters, beginning to be closely studied so we don't know too much about them, but they look as though they could be fairly important. These are behavioral-integrative effects which may not directly involve major physiological disruptions in the organism but are reflected in the inappropriate behavioral responses to either biotic or abiotic factors in the natural habitat, either as a direct result in response to the presence of oil, or as an indirect effect resulting from the masking or mimicking of natural chemical cues by specific components of the oil. For these effects to occur, concentrations in the low parts per billion range may be sufficient to evoke responses and have been indicated in a number of studies.

Oil pollution biology is a relatively new and active field as evidenced by the rapidly accumulating literature on the subject. Virtually all of the available information at present on the

Percy, Grainger, Barry,
Sergeant, Smith, Stein
In Chief

1 effects of crude oil on marine organisms in communities
2 is derived from studies involving tropical and temperate
3 ecosystems. The purpose of this present summary is
4 not to provide an exhaustive survey of this growing
5 literature, but rather to present a general conceptual
6 framework upon which the fragmented information about
7 oil effects on the Arctic marine environment can be
8 viewed to maximum advantage.

9
10 Few Arctic oil spills have been
11 studied in sufficient detail and for a long enough
12 period to realistically assess the environmental impacts
13 of such incidents. A complete absence of pre-spill
14 baseline data has, in most instances, served to further
15 compound the uncertainty. Impact prediction is rendered
16 virtually impossible by the fact that little reliable
17 information, as I pointed out before, is available
18 about the basic ecology and physiology of the great
19 majority of Arctic marine species.

20 Any discussion of oil impact
21 in the marine Arctic must necessarily, therefore, rely
22 heavily upon information accumulated in the many excell-
23 ent follow-up studies of oil spills in temperate seas and
24 in the many laboratory studies that have been conducted
25 on temperate species. However, a considerable caution
26 is required in using this temperate derived information
27 in the Arctic context. Several features of the Arctic
28 marine ecosystem may have an important bearing upon the
29 ecological consequences of an oil spill.

30 Major crude oil spills in
temperate waters such as the Santa Barbara spill in

Percy, Grainger, Barry,
Sergeant, Smith, Stein
In Chief

1 California and the Torrey Canyon spill off the southern
2 coast of England, killed large numbers of birds and
3 intertidal invertebrates, but were not as ecologically
4 devastating to animals in the water column as antici-
5 pated. However, this should not make us overly compla-
6 cent about the potential impact of comparable oil spills
7 in the Arctic Ocean.

8
9 I'd like to consider now,
10 some of the various factors that influence the
11 environmental impact of an oil spill. Studies on the
12 impact of petroleum pollution upon marine ecosystems often
13 yield conflicting and inconclusive results that make
14 it very difficult to establish general principles. That
15 this is so, is largely due to the very complex nature of
16 the pollutant, both in its chemical and physical
17 characteristics, and to the diverse physiological
18 responses of different types of organisms to various
19 components of the oil.

20 Much of the difficulty in
21 predicting oil spill effects is attributable to the
22 fact that the ultimate fate of each spill is determined
23 by several interacting variables, each of which may
24 play a lesser or greater role in influencing the impact
25 upon the ecosystem. Several of these factors are
26 common to Arctic and temperate oil spills, others have
27 important Arctic aspects while some have features that
28 are particularly unique in the Arctic context. For
29 convenience, I have separated them into physical and
30 biological catagories.

The physical factors that are

Percy, Grainger, Barry,
Sergeant, Smith, Stein
In Chief

important are:

1. Type of oil
2. Dose of oil
3. The manner of introduction of oil into the environment.
4. The physiography and hydrography of the spill area.
5. The season of the spill.
6. Weather conditions, and,
7. The method of treatment.

Some of the important biological variables include:

1. The season of the spill, in relation to the to the biological components.
2. Adaptation effects.
3. Interaction or synergistic effects.
4. The nature of the biota present in the area, and,
5. The precise mode of interaction of the oil with the animals.

It's the interaction of all these factors in the Arctic marine environment that will determine the overall impact of any given oil spill. In some spills one or two of these factors may assume an overwhelming importance in determining the magnitude of the impact. For example, just to cite a few examples of this, in the Torrey Canyon spill, the method of treatment was one of the principle contributing factors to the damage that was observed. In the Buzzards Bay oil spill, near -- in Massachusetts it was the type of oil that was particularly damaging because it was a very toxic refined product. In the "Tampico Maru" oil spill, off

Percy, Grainger, Barry,
Sergeant, Smith, Stein
In Chief

the coast of California, it was largely the physiography of the spill area that was the most -- was the determining factor because the spill occurred into a small cove that was then effectively blocked by the tankers so the oil was confined in this small cove, so this was the prime determining factor in that situation.

I'd like to briefly discuss some of these factors from the point of view of oil spills in Arctic waters, the physical factors I'll go over fairly rapidly because I'm not really that competent to interpret the -- some of the physical effects, but I will just mention some of the variables.

The type of oil, firstly. The type of oil spilled in an accident clearly has a major bearing upon the magnitude of the resulting ecological impact. Petroleum pollutants generally fall into two very broad categories. Non-persistent pollutants include the lighter refined components such as gasoline, kerosene, diesel oil, etc., that have generally been found to evaporate rather quickly following a spill. Persistent pollutants such as crude oil, bunker fuel, etc., have a large bulk of heavy components that may remain in the environment for an indefinite period of time. In the absence of far northern refining facilities at present it is the latter type of pollutants that are the most serious threat to Arctic ecosystems. It is generally assumed that the toxicity of refined products is greater than that of crude oil, however Butler and Berkes, after an extensive review of the literature suggest that the available data does not warrant such

Percy, Grainger, Barry
Sergeant, Smith, Stein
In Chief

1
2 a conclusion. Shelton, however, maintains that apart
3 from the light refined components, petroleum products
4 are not highly toxic. This would also appear to be
5 the general conclusion to be drawn from the extensive
6 series of studies that followed upon the Torrey Canyon
7 incident in which crude oil was spilled. However, toxic
8 effects of crude oils have been widely reported and
9 much of the confusion evident in the above few sentences
10 no doubt arises from the fact that different types of
11 crude oil vary quite extensively in their toxicity,
12 as Ottway has clearly shown for several species of
13 intertidal organisms, and as Kuhnhold has similarly
14 shown for crude oil toxicity to herring eggs. Up until
15 the present Beaufort Sea study we had no real indication
16 of the relative toxicity to Arctic marine organisms of
17 northern crude oils.

18 The second physical variable
19 is the dose of oil. That the quantity of oil spilled
20 in a given incident markedly influences environmental
21 impact is so obvious that little comment is required.
22 Other evidence has been presented, I think, that indi-
23 cates the potential dose involved in the quantities of
24 oils that are being considered in the present situation.

25 Thirdly is the manner of
26 introduction of oil into the environment. The fact
27 that the oil will be released into the water from the
28 sea floor under very high pressure, rather than released
29 relatively passively onto the sea surface, is likely
30 to have important consequences in regard to the distri-

Percy, Grainger, Barry
 Sergeant, Smith, Stein
 In Chief

bution of oil in the various parts of the environment,
 that I mentioned before.

Fourthly, the physiography
 and hydrography of the spill area. Coastal configura-
 tion, current flows, tidal conditions and physical
 characteristics of the water column will all play a
 major role in determining the magnitude of the area of
 the marine environment affected by a major spill.

Fifth, is the season of
 the spill. That the seasonal changes in certain physical
 parameters such as temperature or ice-cover, may influence
 the impact of an oil spill is obvious. Not so obvious
 is the fact that the susceptibility of animals to
 certain pollutants may vary considerably with season
 as a consequence of changes in the physiological con-
 ditions of the animals and this has been shown in a
 number of studies in temperate waters. Nothing, how-
 ever, is known about seasonal variations in the
 sensitivity of Arctic animals to crude oil.

Next are weather conditions.
 Obviously, weather conditions at the time of a major
 spill, particularly such factors as wind speed and
 direction, will play an important role, not only in
 determining the magnitude of the area affected, but
 also by influencing sea state in determining the quantities
 of oil mixed in the water column.

Next is the method of treatment.
 The manner in which the spilled oil is treated during
 clean-up attempts is an important feature in determining

Percy, Grainger, Barry,
Sergeant, Smith, Stein
In Chief

1 biological impact. This was one of the major lessons
2 learned from the Torrey Canyon spill, where the use
3 of dispersants appears to have caused more ecological
4 damage than did the oil itself.
5

6 Next are the adaptation and
7 synergistic or interacting effects. Adaptation and
8 interacting effects may subtly modify the impact of
9 oil pollution on a given marine population. Studies in
10 temperate regions suggest that some species can adapt
11 to continued low exposure or continued exposure to
12 low levels of petroleum and thus exhibit greater tolerance
13 to more massive doses, and the particular study that
14 I'm referring to here is one that was done in California
15 where there are certain natural oil seeps and it was
16 found that animals from these oil seep areas appeared
17 to be able to tolerate oil more readily than animals from
18 non-seep areas. This is still a point of considerable
19 contention, but it does appear to occur in certain
20 species.

21 On the other hand, prior or
22 simultaneous exposure of the animals to other types
23 of pollutants may serve to increase the animals suscept-
24 ibility to petroleum. This is just a case of imposing
25 one pollutant stress upon another pollutant stress.
26 However, in view of the relatively unpolluted state
27 of the Arctic Ocean, neither pre-adaptation nor inter-
28 acting effects are likely to play significant roles in
29 modifying responses to oil spills.

30 Next is the nature of the biota.

Percy, Grainger, Barry,
Sergeant, Smith, Stein
In Chief

1
2 There is a marked difference
3 in the ability of different types of animals to tolerate
4 the presence of oil in their environment. Even allowing
5 for the different types of oil and different preparative
6 and experimental techniques, one is forced to the con-
7 clusion that certain species can thrive in incredibly
8 high concentrations of oil, while other species are
9 killed or severely stressed by even a hint of petroleum
10 in their environment. The precise reasons for this
11 remarkable difference in tolerance are not, at present,
12 know; largely due to the fact that we have no very clear
13 idea of which components and what mechanisms of toxicity
14 are responsible for the irreversible damage to organisms
15 exposed to a given crude oil.

16 Data on sensitivities of various
17 species to oil pollution have been derived from two
18 different sources; field observations following accident-
19 al or controlled oil spills and laboratory toxicity studies
20 conducted under standardized environmental conditions.
21 The former are usually difficult to interpret because
22 of lack of controls and the potential involvement of a
23 wide range of uncontrollable environmental variables
24 that may modify the overall response of the oil.

25 On the basis of the available
26 data, it is difficult to draw hard and fast generaliza-
27 tions regarding the oil tolerance of various classes
28 of invertebrates. Difficulties in making comparisons
29 arise from the fact that differences in the tolerance of
30 species are obscured by differences in the oils involved,
differences in method of application of the oils,

Percy, Grainger, Barry,
Sergeant, Smith, Stein
In Chief

1 differences in the degree of weathering of the oils,
2 in addition the differences in a variety of other
3 environmental parameters.

4 The last variable is the
5 mode of interaction of oil with the organisms. The
6 manner in which the spilled oil interacts with the
7 organisms is an important factor in the overall impact
8 of the oil spill. As I pointed out earlier, crude
9 oil, unlike a lot of other pollutants, does not spread
10 uniformly through the environment from its point of
11 release, so the dose of oil to which a given population
12 of animals will be exposed varies considerably, and often
13 unpredictably in different parts of the ecosystem.

14 The physical form, eventual
15 fate and ecological effects of spilled crude oil will
16 differ greatly depending upon whether the oil is
17 deposited in the intertidal zone, dispersed in the
18 water column, absorbed into the bottom sediments or
19 accumulated in pools under the ice.

20 I'll discuss some of these
21 particular habitats and the impact of oil in the later
22 presentation.

23 Now, I'd just like to review
24 some of the biological effects of crude oil and break
25 down some of the generalizations that I made a bit
26 earlier.

27 Blumer, in reviewing some of
28 the potential biological effects of oil pollution in
29 marine ecosystems, suggested that adverse effects upon
30 organisms can be conveniently grouped into the following

[illegible]

Firstly, the direct kill of organisms by physical effects such as smothering or being trapped in the oil.

Thirdly, direct kill of organisms by seawater soluble components.

Fifth, destruction of the food resources of the particular species you're considering.

Seventh, interference with subtle behavioral and integrative mechanisms of individuals, populations or communities.

The greatest emphasis thus far has been placed upon short-term lethal effects of the types outlined in the categories one to four above. Toxicity tests have usually involved either immersing the animals in whole oil for specific periods and then returning them to clean seawater, or more

There is now limited but convincing evidence that crude oil released into the environment not only disrupts normal physiological functions of individuals, but may also interfere with

Percy, Grainger, Barry,
Sergeant, Smith, Stein
In Chief

1 complex behavioral patterns necessary for effective
2 integration of the various components of an eco-
3 system. This may be a consequence of a direct response
4 to the presence of oil or an indirect effect resulting
5 from the masking or mimicking of natural chemical cues
6 by certain soluble components of the oil.

7
8 Kittredge, and others,
9 have pointed out that the effects of the latter type
10 could impair the organisms ability to locate food,
11 to locate a suitable niche or sexual partners and
12 various other subtle effects. However, before further
13 advances can be made in this area by pollution
14 biologists, it will be necessary to have much more
15 comprehensive information on the utilization of these
16 natural chemical cues by marine organisms and this
17 is a fairly young and growing field so the pollution
18 aspects of it are even more uncertain at present. But
19 the indications are that it is a significant phenomenon.

20 THE COMMISSIONER: Dr. Percy,
21 when you're conducting an Inquiry like this as I am,
22 you have to say to yourself from the very beginning
23 that you will not be afraid to ask stupid questions
24 and, confronted with people of your competence, I'm
25 afraid that sometimes I have to ask questions that may
26 seem pretty elementary to you, but I'll continue to do
27 so. Would you mind just telling me -- you said that
28 there were three areas of the waters that were important.
29 You said the intertidal area, which I comprehend, the
30 water column, which I don't think I do and I'd like
you to tell me what that is.

Percy, Grainger, Barry
Sergeant, Smith, Stein
In Chief

1
2 A Basically I split it up
3 into four areas. What I've tried to do is generally
4 assume that if we dump oil into sea water that you're
5 getting so much oil and so much sea water and it has
6 an impact on the ecosystem. What I've tried to do, is
7 to emphasize the fact that this oil is not dispersed
8 uniformly through the ecosystem; it's getting into
9 specific parts and in those parts there are various
10 organisms in these habitats that are likely to be
11 affected. The four sections that I split it up into,
12 and this is sort of a fairly rough splitting, is the
13 inter-tidal zone, the sub-ice community which is the --
14 which I'll be expanding a bit later, the water column
15 which is the water between the surface and the bottom,
16 and then the bottom community, the sediment community
17 and there are animals living in all of these various
18 zones.

19 Q All right.

20 A And I'll be expanding
21 a bit more in the second portion on these various
22 communities.

23 Q I thought that was what
24 you meant, but I wanted to be sure. Now just one other
25 thing and maybe you'll be coming to this later, but
26 I suspect there may well be others in the room who don't
27 understand fully what masking or mimicking of natural
28 chemical cues amounts to.

29 A Well, to give you an
30 example, one of the studies that was done on investigat-

Percy, Grainger, Barry
Sergeant, Smith, Stein
In Chief

1
2 ing this particular point involved the feeding responses
3 in crabs, and it's known that certain chemicals in the
4 water column generally released by the prey organism
5 induce a feeding response in these crabs. Now if the
6 animals had been exposed to very low concentrations of
7 oil in the water column they were unable to detect the
8 presence of these prey chemicals in the water. In other
9 words, it didn't induce their normal feeding response.
10 That's essentially masking of the normal chemical cues
11 present in the environment.

12 We're only now really learning
13 about how wide-spread these chemical cues are. A lot of
14 organisms rely on these water-borne chemical cues for
15 various functions, and various components of the oil --
16 and you've got to remember, too, another important
17 point is that oil consists of thousands of different
18 organic entities, it's not just a nice well-defined
19 entity, and a lot of these are organic components that
20 interfere with the organisms' normal chemo- sensor
21 responses.

22 Now the other aspect that I
23 mentioned was mimicking, and perhaps the best example
24 of this I can give is a fairly well-known fact that
25 lobsters are attracted to certain components of
26 kerosene, and I gather from speaking to various people
27 down the east coast that lobster fishermen frequently
28 make use of this, they soak kerosene or use kerosene
29 soaked rags in their traps. This, presumably some
30 component is being perceived by the lobsters, something

Percy, Grainger, Barry
Sergeant, Smith, Stein
In Chief

1
2 comparable to food, it's receiving a chemical cue from
3 some component of this oil and it's responding as
4 though ~~it~~ were a chemical cue for food. This, in fact,
5 was one of the suggestions why there was such a
6 massive lobster mortality in conjunction with the
7 Woods Hole oil spill, or the Buzzard Bay oil spill, is
8 that the lobsters were in fact attracted to this be-
9 cause it was mimicking what they would normally respond
10 to as a natural cue.

11 THE COMMISSIONER: All right,
12 thank you very much.

13 MR. BAYLY: Q Mr. Commissioner,
14 I propose to ask Dr. Grainger if he would read his
15 evidence next and we'll come back to Dr. Percy after
16 that. Dr. Grainger?

17 WITNESS GRAINGER: The
18 Arctic marine environment is characterized by cold water,
19 the sea ice cover which prevails over a large part
20 of each year, by little penetration of sunlight beneath
21 the sea surface during most of each year, and by a
22 very highly developed seasonality in a large number of
23 features.

24 These features are the ones
25 perhaps more than others, at least which set the Arctic
26 marine environment aside from warmer water regions
27 all over the world.

28 I'm going to refer now to a
29 figure, figure 1, which I attached to the copies, and
30 perhaps if you look at the figure rather than following

Percy, Grainger, Barry
Sergeant, Smith, Stein
In Chief

1
2 the words in the text it will become more meaningful
3 to you. The object in drawing the figure is to show
4 you in this form something of the structure of the
5 ecosystem, which was referred to by Dr. Percy a number
6 of times, a few minutes ago, and to relate different
7 elements of it into a single hole.

8 In the figure then, the hori-
9 zontal scale shows the span of a single year, running
10 from January on the left to December on the right, and
11 the vertical scales show various of the qualities
12 measured. Quantities may be ignored on the vertical
13 scale, the point of it all is that that is increased
14 as we go up the scales from the bottom toward the top.

15 In the lower left in the
16 figure the thickness of ice cover and snow cover over the
17 ice are shown to reach their maximum during May, and
18 then to fall off rapidly in June, and the ice disappears
19 according to this picture by July. With the thinning
20 of the ice, sunlight penetration of the water increases,
21 in fact the sun begins to penetrate through the surface
22 of the sea and this is shown in the figure as light at
23 a depth of five meters. Again this is simply arbi-
24 trarily chosen. Consider that as light under the
25 surface of the water. The peak of this quantity is
26 reached in July, as the ice disappears. It's fairly
27 obvious, I think, that without an ice cover the peak
28 of this would occur around the 21st of June, which of
29 course is the time when daylight is greatest during
30 the year. It then falls off gradually after the

Percy, Grainger, Barry
Sergeant, Smith, Stein
In Chief

1
2 date indicated on the figure.

3 With the increase in the
4 availability of light beneath the surface of the
5 water, the small single-celled marine plants, the
6 phytoplankton shown here as chlorophyll a on the
7 figure, these grow and reproduce and reach their
8 seasonal maximum in quantity soon after maximum light
9 is reached. These plants undergo photosynthesis,
10 in which they use the energy of available sunlight
11 to convert inorganic chemicals present in the water
12 into organic materials which in fact is themselves,
13 and in which they produce oxygen.

14 One of the inorganic substances
15 they use is a compound containing nitrogen and this is
16 shown as nitrate in the figure. This increases in
17 quantity during winter in the sea, as indicated, when
18 plant activity is almost totally stopped under the
19 sea ice cover. There is production but almost no
20 utilization. With the development of plant activity in
21 May - June, nitrate begins to decline in quantity and
22 continues to do so until the plants reach their peak in
23 August. The plants -- the chlorophyll a, again, in
24 the figure, are the food of the small plant-eating or
25 herbivorous zooplankton.

26 These increase their numbers
27 with the production of young animals as plant food
28 becomes available in early summer and the numbers fall
29 off through the late summer and autumn, as shown in
30 the figure. The decline in chlorophyll in this figure

Percy, Grainger, Barry,
Sergeant, Smith, Stein
In Chief

1 was probably mainly a result of predation by the zoo-
2 plankton -- of the plankton feeding on the plants. The
3 fall in numbers of zooplankton was, in turn, probably
4 initiated by larger animal eating carnivorous zooplankton
5 and fishes which are not shown in the figure. Toward
6 the right of the figure then, through October and Novem-
7 ber, winter conditions developed once more. In December
8 the sea ice cover formed, began to grow and we were back
9 close to the situation shown in the previous January.

10 The several stories shown in this
11 figure, all of which are bound together and part of
12 the much larger one, are not based upon data obtained in
13 the Beaufort Sea, but the great seasonality in-
14 dicated by the high peaks and the low dips in the figure,
15 and the major lines of dependence in the Arctic region
16 shown here, certainly relate, very obviously to the
17 Beaufort Sea. Our study in the Beaufort Sea didn't
18 allow the presentation of this kind of year-round informa-
19 tion, in fact, which came from the eastern Canadian
20 Arctic.

21 No part of the actual Beaufort
22 Sea Project open-water study, and this applies to the
23 work undertaken in 1974 and 1975, as part of the project
24 which I was concerned in, was carried out under favorable
25 circumstances. The ship-supported surveys of the two
26 summers failed so badly to achieve the schedules planned
27 for them, that most of the data strength of the study
28 originated therefore, either in the year preceding the
29 initiation of the Beaufort Sea project or through the
30 use of helicopters on the early summer sea ice cover.

Percy, Grainger, Barry,
Sergeant, Smith, Stein
In Chief

1 This was largely the consequence of sea ice persisting
2 over areas where studies from shipboard had been
3 planned. It had important consequences to this study
4 showing in a very clear way, the fallacy of underestimat-
5 ing the Arctic by presupposing a capacity to perform in
6 it under all conditions.

7 THE COMMISSIONER: Did that,
8 Dr. Grainger, I understood in 1974 the sea ice persisted
9 longer than had been expected. Was that so in 1975 too?

10 A Both yes and no, if that's
11 fair. There were problems locally with sea ice which we
12 experienced in our ship as a consequence of which we were
13 unable to complete or even to visit most of the planned
14 station points.

15 THE COMMISSIONER: Dr. Pimlott
16 said, and I recollect being in the delta in the summer
17 of '74, and, he said that in that summer -- that was the
18 summer when summer virtually didn't come to the Beaufort
19 Sea. Last summer was a normal summer in terms of the
20 general climatic conditions, but I gather that localized
21 conditions prevented you from carrying out the work you
22 planned to. Is that what you are saying?

23 A Yes. We had a period planned
24 for use of one of the ships and while I believe the weeks
25 preceding our use of the ship were quite clear from the
26 point of view of ice, during the few days we were onboard
27 much, at least there was a large shoreward movement of
28 pack ice which, during that period of time, prevented our
29 visits to the planned points.

30 The present investigation did,

Percy, Grainger, Barry,
Sergeant, Smith, Stein
In Chief

1 in fact, not achieve it's expectations in terms of range
2 of coverage either in space or in time. And a number of
3 rather elementary questions concerning base-line features
4 of this system therefore, remain unanswered. The
5 essentially base-line studies which I'm reporting on here,
6 were concerned for the most part with the sequence of
7 relationships shown in figure one. The "lower" end of
8 the ecosystem on which the fishes, sea birds, seals and
9 whales are to such a great degree dependent.

10 It must be pointed out here, even
11 though the physical oceanographers may already have done
12 this or may, in fact, now be doing it in the future,
13 but much of the coastal portion of the eastern Beaufort
14 Sea is estuarine in its nature. This means that the
15 relatively warm -- in the summer - fresh water of the
16 Mackenzie River, flows beyond the river mouth largely over
17 the colder, saltier, and therefore heavier, water of the
18 Beaufort Sea. This area of visible river influence, made
19 especially obvious in the Beaufort Sea by the heavy silt
20 load carried seaward by the Mackenzie, is highly variable
21 in its size, shape and location. Driven offshore by
22 southerly winds, it is at its largest and it extends
23 under those conditions farthest from shore.

24 Following onshore winds, the
25 fresh water area is reduced in extent and forced shore-
26 ward, often close to the Tuk Peninsula coast. Largely
27 because of its silt load, light penetration is greatly
28 inhibited in the low salinity water just off the river
29 mouths. Outside this area of primary river influence,
30

Percy, Grainger, Barry,
Sergeant, Smith, Stein
In Chief

1 the clear oceanic waters allow fairly deep penetration
2 of light. Whereas in the river water region, nutrients
3 are abundant -- nitrate for instance -- having been
4 contributed by river flow, they are largely useless in
5 terms of supplying nutrients to the plants because the
6 silt of the water at that point inhibits the penetration
7 of light and consequently the plants are unable to carry
8 out their photosynthesis and hence to use the nutrients
9 which are present.

10 Beyond the area of river influence,
11 the river plume, generally sufficient light in summer is
12 accompanied by low nutrient values. Once the relatively
13 small winter produced supply is used up, the surface
14 waters become nutrient poor. So after the first bloom
15 of spring, plant production largely stops because of
16 nutrient deficiency.

17 The second figure, figure 2,
18 shows light penetration in the southern part of the
19 Beaufort Sea. The area of primary river influence is
20 shown by the low values (one and less) off the
21 delta and off the Tuk Peninsula coast, and the offshore
22 waters by much higher values -- as you can see by looking
23 at the figure -- there are values up to sixty, forty
24 and so on, beyond the river plume.

25 In figure three, which shows
26 nitrate in the upper five meters of the water, that is,
27 between the surface and five meter depth. Nitrate -
28 nitrogen near shore is shown to be highest in approximately
29 the same area as the low light penetration was shown
30 in the other figure, that is to say, just off the river

Percy, Grainger, Barry,
Sergeant, Smith, Stein
In Chief

1 mouths. Much lower values are seen farther offshore.

2 The high values, then, coincide
3 largely with the area of low light penetration; the
4 low values with the area of deep light penetration.
5 In the first named regions, the material is not utilized
6 to any great degree by the plants. In the second area
7 offshore, it is used effectively and rapidly by the
8 plants.

9 Now we can't at present show
10 the -- in any detail -- the geographical distribution
11 of production of plants in the south Beaufort Sea
12 because we weren't able to collect the data adequately
13 to present it that way. But indirect evidence points
14 to lowest values of plant production in the nearly
15 fresh, silt laden waters just off the river mouth. Farther
16 offshore, beyond the river influence, production also
17 seems to be low during much of the summer, for reasons
18 I've already explained.

19 Quantities of plant material in
20 summer are fairly consistently low on the basis of
21 chlorophyll a measurements, in the area of study in the
22 Beaufort Sea. This determination of low, by Arctic and
23 by world standards and the values we found in the Beaufort
24 Sea average, for instance, about one fifth those which
25 we found, at the same time of the year, in a fully
26 marine Canadian Arctic area in the eastern Arctic of
27 Baffin Island -- approximately one fifth the average
28 values.

29 The small zooplankton animals
30 were distributed quantitatively as shown in figure four,

Percy, Grainger, Barry,
Sergeant, Smith, Stein
In Chief

1 which is the last figure. In this, the numbers of
2 organisms per unit of water sampled, are shown by circles
3 of five sizes. The legend is on the top -- the largest
4 black circles indicating the largest numbers and the
5 smallest, the smallest numbers.

6 The highest numbers of individual
7 zooplankton animals were found in the coastal bays;
8 the lowest numbers, nearest the river mouths, and far
9 offshore. Intermediate distances offshore showed inter-
10 mediate values. Now some of the levels measured were high
11 by Arctic standards -- the large circles onshore
12 indicated very dense populations of species -- of speci-
13 mens -- but the great majority were low by all regional
14 standards, and in fact, bore a similar relationship to
15 the Baffin Island quantities, as was shown by the plants
16 above.

17 So, it is suggested on the basis
18 of this kind of information that the south Beaufort Sea
19 is a region of low marine production.

20 Now, considering for a moment
21 some of the more specific studies which were related to
22 this kind of work; crude oils evidently had no effect upon
23 rates of nitrogen fixation of bacteria of the
24 Beaufort Sea substrate -- the bottom of the Beaufort Sea,
25 which is to say that the capacity of the bacteria to
26 transform the element nitrogen, in which form it is not
27 useable by plants, to a form in which it becomes available
28 to parts of the biological cycle, does not seem to
29 have been altered by short term exposure to oil, based
30

Percy, Grainger, Barry
Sergeant, Smith, Stein
In Chief

1 on experimental work carried out. Natural fixation rates
2 appeared to be extremely low in Beaufort Sea samples, but
3 were experimentally accelerated by the addition of
4 carbon compounds, showing a potential which the natural
5 conditions evidently did not allow to be realized.

6 In a similar way, denitrification,
7 which is the return to elemental nitrogen, from the
8 useable nitrogen compounds, was unaffected by oils,
9 as was carbon dioxide production. Carbon dioxide
10 production was measured here simply as a means of showing
11 general metabolic activity of the bacterial cells.

12 Examination showed an abundant
13 population of heterotrophic bacteria. That is, bacteria
14 utilizing complex organic materials in their metabolism.
15 The large population was shown to have oil degrading
16 potential in the Beaufort Sea. Largest cell counts were
17 made in surface river water north of the Tuk Peninsula.
18 Laboratory culturing showed that all the areas of the
19 Beaufort Sea sampled supported bacterial populations with
20 a potential for biodegradation at 5°C. In fact, a
21 biodegradation potential was found at as low a temperature
22 as -1°C. Nitrogen may be the principal limiting
23 nutrient affecting metabolic activity of these bacterial
24 organisms.

25 The effects of four types of
26 crude oil -- Atkinson Point, Norman Wells, Pembina and
27 Venezuela -- on phytoplankton productivity rates varied
28 from inhibition to stimulation, depending not only on the
29 species of plants, but as well on location, duration of
30 the experiment, concentration of oil and the use of

Percy, Grainger, Barry,
 Sergeant, Smith, Stein
 In Chief

dispersants. The use of Corexit with crude oils generally inhibited productivity.

Two seaweed species were examined for the effects of oil and productivity of both was found to be significantly inhibited by all types and concentrations of oils tested.

The threads that tie these studies together are the lines that run through the ecosystem under study, the fundamental dependence of each level upon those below it in the system structure. A major line of energy transfer is the food chain, and this is a pathway for pollution. The primary plants utilize inorganic nutrients (nitrogen, phosphorus, silicon) and sunlight in the synthesis of organic material. This was mentioned a few moments ago. These, in turn, are the prey of plant-eating zooplankton, mainly small copepods. Next, come the predatory zooplankton -- the carnivorous -- a few larger copepods, but mainly jelly fishes, comb-jellies, arrow-worms and other large predatory forms, and finally, pelagic fishes in the Beaufort Sea, principally the Arctic cod.

Other fishes prey on larger zooplankton and on small fishes, and the mammals on the larger invertebrate animals and on fishes. Within this scheme of things, the bottom-dwelling invertebrates exist and they subsist mainly on the rain of detritus from above and on other elements from the plankton above, as well as on each other -- and of course, they are the prey of the larger bottom animals, including fishes and bottom-feeding mammals.

Percy, Grainger, Barry,
Sergeant, Smith, Stein
In Chief

1 It is a characteristic of
2 cold northern waters that the number of species of
3 plants and animals is small, relative to what is found
4 in warmer seas, but that proliferation of individuals
5 of certain of the few species is great. Hence, we have
6 a small number species, a few of which are dominant and
7 account for the large majority of the individuals. This
8 is a simple system, at least according to one method
9 of assessing simplicity, compared to one in which the
10 total diversity is greater and none of the species is
11 dominant. Relationships based upon who eats whom are
12 simply illustrated in the Beaufort Sea. They show that
13 the chains are usually short and have few links. Typical
14 sequences are diatom -- this is a plant, phytoplankton
15 cell -- diatom to copepod to fish. That's a three linked
16 chain. Diatom to copepod to amphipod to seal; flagellate
17 to euphausiid to whale, that sort of thing. Options in
18 these energy pathways are few and vulnerability is there-
19 fore high.

20 One extremely important part of
21 the system, significant in food chain building, is the
22 under-ice biota. This is a feature of Arctic seas, the
23 response to the ice cover which overlies the sea for a
24 long part of each year. A special flora, comprised of
25 diatoms, develops under the ice as winter progresses
26 and the ice thickens. Evidently using nutrients available
27 in the ice, the cells grow and divide, forming dense
28 concentrations on and just within the lower surface of
29 the ice. These plants may account for a significant
30 proportion of total primary carbon production in a region,

Percy, Gradinger, Parry,
Sergeant, Smith, Stein
In Chief

1 over a year. The flora provides a large upside down feed-
2 ing surface for small planktonic animals and forms the
3 base of a food chain which includes the Arctic cod,
4 probably the most important pelagic fish in the Beaufort
5 Sea, as well as seal and whales.

6 Fixed in position, rather like
7 an upside-down sea bottom community, the under-ice
8 flora would appear to be highly vulnerable to oil
9 effects, on the basis of a total lack of avoidance capacity
10 and of the effects of oil on most plants cultured in the
11 laboratory, as this has been shown in the experimental
12 work done so far. If significant disruption of the under-
13 ice flora occurs, then the effects may be expected fairly
14 quickly to extend through the ice-based food chain.

15 Partly fixed in position are many
16 members of the sea bottom fauna. Some move only very
17 slowly, hence have only low capabilities for avoidance.
18 Some move fairly quickly, but even they are restricted to
19 a two dimensional surface, and cannot leave it, at
20 least for any significant length of time. Especially in
21 shallow bays, these populations are in a highly vulnerable
22 position as a consequence of oil impact. Their role as
23 food is particularly important to the bottom fishes and
24 perhaps to diving birds and sea mammals.

25 It's been suggested before that
26 biological systems are complex and highly variable.
27 Of course they are. Whole systems undergo seasonal and
28 annual variations. More troublesome are the highly
29 individual variations found in different species and
30 within single species at different periods of their cycles

Percy, Grainger, Barry,
Sergeant, Smith, Stein
In Chief

1 and under an almost overwhelmingly large number of
2 other variables related to their physiological conditions
3 and their external circumstances. This point was made
4 a few minutes ago, of course, by Dr. Percy.

5 As a start, it is absolutely
6 essential that we derive a considerable degree of
7 understanding of undisturbed or "normal" systems before
8 we can appreciate many of the impact effects in any full
9 sense. There is a requirement here for a great deal of
10 work which must extend over a fairly long period of
11 time.

12 In the Beaufort Sea and in most
13 of the remaining marine areas of the Canadian Arctic,
14 there are requirements to study ecosystems over periods
15 of several years, and in all seasons of those years, to
16 demonstrate normal annual and seasonal variations in all
17 levels of the systems, and to define the major governing
18 factors which make the systems go.

19 Superimposed over this are
20 studies designed to respond to specific anticipated
21 impacts, many of them, in their relevance to a particular
22 system, dependent upon knowledge of the basic system
23 itself.

24 In the Beaufort Sea, for instance
25 there is no evidence at present that crude oil contamina-
26 tion of short duration will influence nitrogen fixation
27 or denitrification by bacteria in the sea bottom. There
28 is, however, the possibility of long -term effects, and
29 there is a need for examination of this possibility.
30 This is a recommended future task, important in any case

Percy, Grainger, Barry,
Sergeant, Smith, Stein
In Chief

1 but with the significance possibly increased by our
2 knowledge of the long term natural rates of these
3 activities in the sea bottom, their dependence upon
4 variable nutrient supplies, and their overall role in
5 the biology of the system, all matters about which we
6 know very little, at the moment. Here a recommended
7 impact study could be greatly enhanced in its signifi-
8 cance by additional work of a basic nature. The two
9 approaches are not at all clearly distinguishable; in
10 environmental studies, they may, in fact, be quite inter-
11 mixed.

12
13 There is a requirement to learn
14 about rates of degradation of oil by bacteria under varying
15 circumstances. How large a spill may be reduced during
16 what time period? There is a direct potential impact
17 effect in this. But, assessment of destruction rates
18 is also dependent upon the basic populations present at
19 the time of impact and upon the factors which control
20 bacterial populations in the natural system.

21 There is a special need to
22 study biodegradation under the sea ice. At present, we
23 have no knowledge about bacteria naturally occurring
24 there, and we must learn about them as part of the normal
25 system.

26 Crude oils inhibit productivity
27 and growth of phytoplankton under many but not all
28 circumstances, in the laboratory. There is a need
29 to understand these interactions. Effects of stress
30 may be expected to vary widely, on different species,
and on single species under a range of physiological and

Percy, Grainger, Barry
Sergeant, Smith, Stein
In Chief

1 environmental conditions. Normal population interactions
2 and life cycles of species are a pre-requisite to under-
3 standing additional impact stresses.

4 The whole ecosystem is vulnerable
5 through food chains. Our knowledge of them is at least
6 quantitatively rudimentary.

7 Spread of impact effects is
8 enhanced by the eustuarine nature of the Beaufort Sea
9 in which river water is spread over the underlying sea
10 water in a rapidly changing pattern. There is a need
11 for expanded base line data both in time and space,
12 to give better knowledge of background physical factors
13 which effect water movement at all depths.

14 Much more must be known about
15 the sea ice flora, its conditions of life and its predators
16 which forms the base of a far-reaching and therefore
17 important ice-based food chain.

18 MR. BAYLY: Mr. Commissioner,
19 would this be an appropriate time for coffee?
20

28 MARKED EXHIBIT 448)

29
30 (PROCEEDINGS ADJOURNED AT 11:30 A.M.)

Percy Grainger, Barry, Sergeant,
Smith, Stein
In Chief

1 (PROCEEDINGS RESUMED AT 11:50 A.M.)

2 MR. BAYLY: Mr. Commissioner,
3 before we begin with Dr. Percy's second portion of
4 evidence, there are two matters. At first, originally,
5 Dr. Sterling was to be on this panel, and he arrives
6 tomorrow, and if there are no objections tomorrow
7 morning, if there are no objections from other
8 participants or from you, sir, I would propose to add
9 him on to the end of the table, and have him give his
10 evidence in chief and be available for cross-examination
11 with the others.

12 THE COMMISSIONER: Fine.

13 MR. BAYLY: I've asked Dr.
14 Grainger if he could perhaps give an explanation of a
15 couple of terms that he used, for the benefit of all.

16 Q Dr. Grainger, there were some
17 terms used in your evidence in chief that perhaps you'd
18 be good enough to explain. One of these is found on
19 page 5, and it's "natural fixation rates."

20 WITNESS GRAINGER: Yes, that
21 referred to the business of nitrogen fixation by
22 bacteria, which is referred to on the same page, and
23 identified as being the capacity of the bacteria to
24 transform nitrogen into compound, usable compound.

25 Q And on page 6, there's
26 a term, "bio-degradation potential".

27 A Yes. The reference there
28 is to the potential capacity of bacteria to degrade oil,
29 to break down oil, that is a biological break-down of
30 oil.

Percy, Grainger, Barry, Sergeant,
Smith, Stein
In Chief

1 THE COMMISSIONER: I assumed
2 that's what it meant, and I assumed also that that was
3 desirable, or have I got that the wrong way around?

4 A From the point of view of
5 removing oil from the environment, yes sir, that would
6 be desirable.

7 MR. BAYLY: The third term is
8 on page 8, it's "pelagic fish".

9 A "Pelagic" refers to the,
10 really though, to the water column which was mentioned
11 by Dr. Percy earlier; the pelagic animals are those
12 which occupy the space from the surface down to but not
13 including the bottom, which either swim or float; and
14 in the case of fishes it separates those which live on
15 the bottom from those which swim about above the bottom.

16 MR. BAYLY:

17 Mr. Commissioner, were
18 there any other terms that you wished to explore?

19 THE COMMISSIONER: No, those
20 in fact, were some that troubled me.

21 MR. BAYLY: We could go on then
22 to the second portion of your evidence, Dr. Percy.

23 WITNESS PERCY: As I pointed
24 out earlier, relatively little attention is being paid
25 to the ecological effects of development on components
26 of the marine eco-system, that while of little or no
27 direct economic significance, nevertheless constitute
28 the essential foundation of the ecological pyramid upon
29 which these more visible elements are totally dependent
30 for their very existence.

THE COMMISSIONER: Do you mean

Percy, Grainger, Barry, Sergeant,
Smith, Stein
In Chief

1 we are -- by "we" I mean society -- we are worrying
2 about the whales and the seals and so forth, and not
3 about the elements of the lower end of the food chain?

4 A Right. The whole thing
5 has to be considered in total rather than considering
6 just the upper end of the scale.

7 In this paper, I'll primarily
8 be concerned with the direct impact of crude oil upon
9 marine invertebrates. An emphasis will be placed upon
10 some of the sub-lethal effects, that although/difficult
11 to detect and interpret, are nevertheless, of greater
12 ecological significance over the long term, than the
13 more readily observable, rapid mortality of high oil
14 concentrations.

15 As I mentioned earlier, the
16 nature of the specific interaction of oil with the
17 organisms is a very important consideration. Crude
18 oil, unlike many other pollutants, by virtue of its
19 relative insolubility, does not spread uniformly
20 through the environment from its point of release.
21 I'll primarily concentrate upon intertidal oil-- oil
22 in the sub-ice zone, oil in the sediment, and oil
23 dispersed in the water column.

24 The most dramatic and obvious
25 biological damage associated with oil spills in
26 temperate and tropical waters occurs when drifting
27 slicks are driven ashore and blanket large areas of the
28 biologically rich intertidal zone. In most areas of
29 the western Arctic the intertidal zone is depressingly
30 barren of marine life as a result of intense scouring

Percy, Grainger, Barry,
Sergeant, Smith, Stein
In Chief

1 by sea ice. Therefore damage to invertebrate fauna in
2 these areas will consequently be minimal. Such stranded
3 oil is, however, still available for re-introduction
4 into other areas of the marine environment, and should
5 not be considered as completely innocuous.

6 THE COMMISSIONER: Excuse me,
7 could I interrupt you. Maybe we're talking about two
8 different things -- yes, we are, I'm sorry. When Dr.
9 Gunn spoke about birds, he made the point that the
10 area where the land meets the water is particularly
11 important to them.

12 A Right. Yes, I should
13 point out and emphasize that I am specifically referring
14 in this paper to invertebrate fauna, and there will be
15 cases where the effects on birds and on marine mammals
16 will be quite significantly different.

17 THE COMMISSIONER: All right,
18 I'm sorry.

19 A If the oil is released
20 under ice, or transported there by currents, it will
21 tend to accumulate in irregularities in the ice
22 undersurface to form oil lenses of variable size.
23 Accumulation of significant quantities of oil in under-
24 ice habitat may have a number of very important
25 ecological consequences.

26 As Dr. Grainger's pointed out,
27 a rich algal bloom forms on and within the lower
28 surface of the annual ice in the spring. This ice flora,
29 and I'm quoting Max Dunbar here,

30 "forms an important faction of the total production

Percy, Grainger, Barry,
Sergeant, Smith, Stein
In Chief

in the Arctic Ocean and....it helps greatly to
prolong the productive season beyond that
of the water-borne phytoplankton"

In addition, a variety of
marine invertebrates have been observed congregating
in the general vicinity of the ice-water interface.
This algal bloom may serve as an important food source
for some species during the spring, a time when
phytoplankton levels in the water column are rather
low.

Although the algal components
of such sub-ice communities have received considerable
attention recently, little is known about the potential
impact of crude oil on these phytoplankton. Virtually
nothing is known about the general ecology and trophic
inter-relationships of the animal components of this
community and little is known about the sensitivity of
the animals to crude oil. The impact of oil on
organisms in the sub-ice habitat may, in some respect,
be similar to the impact on intertidal fauna in other
areas. In both situations animals are likely to be
subjected to smothering and fouling by viscous oil
masses.

A particularly disturbing aspect
of the accumulation of oil in pockets under and within
the sea ice, is that the trapped oil does not appear
to weather significantly over the course of many months.
The reason generally cited for the relatively limited
impacts of crude oil spills in temperate and tropical
waters is that the oil weathers very rapidly and loses

Percy, Grainger, Barry,
Sergeant, Smith, Stein
In Chief

1 most of the toxic components while drifting as a slick
2 upon the sea surface. This certainly appeared to be
3 the case in the Torrey Canyon oil spill. Clearly this
4 does not happen with ARctic under-ice oil spills. In
5 the present study, the toxicity of oil recovered from
6 the ice six months after being spilled was not
7 significantly lower than that of fresh oil.

8 The recovered oil is, further-
9 more, virtually indistinguishable from fresh crude
10 with regard to viscosity, density, gas chromatographic
11 profile, and various other parameters.

12 This severe reduction in
13 the rate of weathering of trapped oil has two potentially
14 very important ecological consequences; firstly it
15 provides a means of transporting the oil, in both a
16 spatial and a temporal sense, without signifcant
17 diminution of toxicity. Natural ice movements in the
18 Beaufort Sea Gyre could result in the oil being
19 transported considerable distances from the spill site
20 and reintroduced into the water column, still in toxic
21 form.

22 THE COMMISSIONER: Before we
23 go on, just tell us what "BEaufort Sea Gyre" means?

24 A Yes, this is the general
25 circulation of the ice and water in the Beaufort SEA
26 itself. I think it's probably been discussed in Allan
27 Miller's testimony earlier on, the sort of full implications
28 of the Gyre.

29 THE COMMISSIONER: Yes, well
30 that's later on.

Percy, Grainger, Harry,
Sergeant, Smith, Susan
In Chief

A Oh later, I'm sorry, I was under the impression that he'd presented ^{it} already. I'm sorry; but it's the general pattern of clockwise movement of the ice in the Beaufort Sea.

In other words, there would be a little decrease in toxicity with increasing distance from the spill site, as occurs in ice-free waters.

Perhaps of even greater significance is the fact that the oil from a prolonged late summer blowout would accumulate within and under the ice over a considerable period of time. There would be little or no diminution of toxicity with increasing time after release into the environment, as occurs in ice-free waters. Toxic components of the accumulating oil would be preserved unchanged until the spring break up, when some of the oil would be re-introduced into the water column en masse. In view of the initiation of intense biological activity in the upper layers of the water column during the postbreak-up period, this may be the worst possible time of the year for the re-introduction of unweathered oil into the seawater. Planktonic larval stages of many species may be particularly vulnerable at this time of year.

The high sediment load carried by the Mackenzie River into the Beaufort Sea, in the form of a massive and visually impressive plume, poses special problems in terms of the consequences of a major oil spill in the area. The Santa Barbara blowout in California proved rather instructive in this respect. Heavy rains prior to this spill resulted in a heavy

1 run-off that produced large sediment plumes in inshore
2 areas. Oil slicks penetrated only short distances into
3 such plumes, and much of the oil was absorbed on
4 suspended particles and carried to the bottom. In
5 effect, the sediment acted as a natural sinking agent.

6 At the first glance this
7 might appear to be a rather effective self-purification
8 process. In fact, it appears to compound the problem
9 immeasurably. Unlike an oil slick, oil bound to
10 bottom sediments is essentially beyond human control.
11 Sinking does not remove the oil from the ecosystem,
12 rather it concentrates it in one ecologically important
13 part of the marine environment.

14 Little is known about the
15 effects of such oil-contaminated sediments upon benthic
16 epifauna and infauna; and I'm using the two terms here
17 to differentiate between the animals that live above
18 the bottom -- on the bottom but above it -- and animals
19 that actually live within the bottom. So the epifauna
20 is above, and infauna is actually within the bottom
21 sediments.

22 The present studies indicate
23 that certain benthic species are killed by short-term
24 exposure to oiled sediments, but only at very high oil
25 concentrations; concentrations that are unlikely to be
26 realized in the natural environment, except perhaps in
27 very close proximity to a spill. At present we have no
28 information on possible toxic effects resulting from
29 prolonged exposure to sediments tainted with lesser
30 quantities of oil.

Of considerable ecological concern is the fact that certain species are capable of detecting low concentrations of oil in the sediment. Behavioral patterns may be markedly altered in the presence of such tainted sediments.

Blumer suggested that the high lobster mortality associated with one oil spill may have resulted from attraction of animals to the spill site. Our studies indicate that different benthic species respond quite differently to the presence of contaminated sediments. The burrowing amphipod, and these are little shrimp-like animals, *Onisimus affinis*, exhibits a decided preference for untainted relative to tainted sediments. However, there are indications that at high oil levels the animals lose the ability to discriminate, possibly a consequence of chemical impairment of chemoreceptor function. On the other hand, another benthic amphipod burrows readily in both untainted and tainted sediments. Clearly behavioral responses such as these will play an important role in determining the overall impact of pollution upon particular species.

Once the oil is bound into the superficial bottom sediments, it is likely to have a long term effect on the benthic community. Studies in temperate areas suggest that oil trapped in sediments is degraded very slowly, and given the sub-zero temperatures of Arctic marine sediments, the rate of degradation may be even slower. The present study indicates furthermore, that the rate of decline in

Peicy, Grainger, Barry,
Sergeant, Smith, Stein
In Chief

1 toxicity of sediment-bound oil varies markedly with
2 different oil types.

3 Oil contaminated bottom sediment
4 may not be static. SEdiments in the Beaufort Sea are
5 intermittently eroded and redeposited by bottom
6 currents, so that the potential exists for contamination
7 of a much wider areas of sea floor than that affected
8 by the initial deposition. In the Santa Barbara oil
9 spill, oil initially deposited in shallow water was
10 later transported and redeposited in deeper areas. Oil
11 may occur in the water column in both a dispersed and
12 a dissolved state, and it is in these forms that it is
13 likely to spread most widely through the ecosystem, and
14 interact with the greatest number of species. It is
15 generally agreed that the finely dispersed oil is more
16 toxic to marine life than are soluble extract. This
17 may, however, be largely due to the fact that much
18 higher concentrations of oil occur in seawater, in a
19 dispersed form rather than in a dissolved form. The
20 droplets, once formed can be rapidly dispersed over a
21 considerable distance and to great depths, as reported
22 by Freearde and Conover. Several days after the wreck
23 of the tanker "Arrow", subsurface particulate oil was
24 detected some 250 kilometres from the scene of the spill.
25 Berridge and others point out that when oil is the
26 continuous phase, there is no real limit to the extent
27 to which the droplets are able to be dispersed.

28 Little useful information is
29 available about the concentrations of oil to which
30 Arctic midwater species might be exposed, and for what

Percy, Grainger, Barry,
Sergeant, Smith, Stein
In Chief

1 length of time, both critical factors in assessing
2 potential toxic effect.

3 In the case of a 65,000 barrel
4 spill from a drilling rig in the Mississippi delta,
5 the concentration of dispersed oil in the water column
6 ranged from one to seventy parts per million within
7 a one-mile radius of the spill.

8 On the basis of our short-term
9 that we have examined
10 lethal studies most of the species /appeared to be
11 relatively tolerant to high concentrations of dispersed
12 crude oil. Even with what we've called sensitive
13 species, dispersed oil concentrations of 100 parts per
14 million or greater were required to cause significant
15 mortality during four days continuous exposure. It is
16 unlikely that such high concentrations will occur
17 widely in the water column, but may be reached in
18 limited areas in ^{very} close proximity to a spill, or where
19 large accumulations of sub-ice oil are released into
20 the seawater at break up.

21 It should also be kept in
22 mind ^{also} /in extrapolating lab results to a field
23 situation that the experimental toxicity tests reported
24 here were routinely carried out with fresh crude oil
25 that was replaced at 24-hour intervals. Consequently,
26 the experimental results are based on the worst possible
27 exposure conditions that could conceivably occur.
28 Exposure of the oil at the air-sea interface for any
29 length of time would undoubtedly result in a gradual
30 reduction of toxicity through weathering.

In view of the above

Percy, Grainger, Barry,
Sergeant, Smith, Stein
In Chief

1 considerations it appears certain that massive short-
2 term mortality among adult organisms inhabiting the
3 water column, as a result of contact with particulate
4 or sub-particulate crude oil, if it occurs at all, will
5 be limited to relatively small areas. Furthermore, only
6 particularly sensitive species are likely to be
7 severely affected over the short-term, within these
8 areas.

9 I'm just going to interpolate
10 this following paragraph a little bit further down, so
11 I'm going to skip the next paragraph and continue.

12 The short-term lethality studies
13 tend to indicate a rather high tolerance level for crude
14 oil among the various species examined. However, a
15 closer examination of some of the more subtle sub-lethal
16 effects upon physiological functions, suggests that
17 the oil may not be quite as benign as it first appears.
18 Such sublethal effects may directly result in the death
19 of organisms over an extended period, or more insidiously
20 may impair the animal's ability to withstand normal
21 environmental stresses. Two measures of physiological
22 function useful for investigating sublethal effects are
23 respiratory metabolism and locomotory activity. Both
24 may be severely impaired by exposure to low concentrations
25 of dispersed oil. We are still not in a position, at
26 the moment, to state with any degree of confidence,
27 ^{actual} the long-term ecological consequences of such
28 physiological changes, even though we do know that they
29 occur. An exposure that rapidly kills the animal is
30 clearly significant. It is considerably more difficult

Percy, Grainger, Barry
Sergeant, Smith, Stein
In Chief

1 to demonstrate unequivocally, that a 30% reduction in
4 metabolic rate or a 50% reduction in activity has adverse,
3 long term effects on a population. The effects are subtle,
4 and the ultimate consequences are very much influenced
5 by a wide range of inadequately known factors.

6 Species differences were evident
7 in the behavioral responses to the presence of crude oil.
8 As I mentioned earlier, certain species appeared to be
9 totally indifferent to the presence of the oil and
10 readily ingested oil-tainted food and burrowed in oil
11 contaminated sediments.

12 In marked contrast, a number
13 of other species exhibited a high degree of aversion to
14 the oil; they tended to avoid oil masses, refused oil-
15 contaminated food, and overwhelmingly selected and
16 burrowed in clean in preference to oil-contaminated
17 sediments. Studies suggest that the animals are capable
18 of responding and detecting very low concentrations of
19 sediment bound oil. These diverse behavioral responses
20 may play an important role in determining the
21 physiologically effective dose of oil to which the
22 specific populations may be exposed. Furthermore, the
23 pronounced disruption of feeding and burrowing behavior
24 noted in some species could have far reaching implication
25 regarding the continued survival of these populations.

26 The use of physiological data,
27 such as the above, acquired under carefully controlled
28 lab conditions, to explain and anticipate biological
29 events occurring in the real world, is a difficult enough
30 exercise at the best of times. In the ARctic, the

1 process is rendered doubly difficult by the fact that
2 our knowledge of conditions in the real world is
3 deplorably inadequate. To be overly dogmatic under
4 such circumstances is to be less than realistic. At
5 best it is possible to hint at simplistic adverse
6 effects on specific populations arising from direct
7 encounter with the oil. We are on far less firm
8 ground in attempting to assess the wider long-term
9 ecological repercussion of these primary effects.

10 It is likely that given the
11 right conditions, some reduction in the diversity of
12 species in the area, as a result of the above lethal
13 and sublethal effects, would occur. This may be a
14 particularly important consideration in the Beaufort
15 Sea and perhaps the Arctic in general. For as Grainger
16 has just pointed out,

17 "the relatively simple population structure
18 in the inshore water suggests a relatively
19 uncomplicated food chain, and this means fewer
20 but relatively more important links in the
21 chain, and therefore greater vulnerability of
22 the whole chain than one would expect in a
23 more complex web."

24 At present, we know too little
25 about Arctic marine food chains to be able to confidently
26 pinpoint critical links that might be particularly
27 subject to disruption by spilled oil. Intensive
28 studies on the trophic inter-relationships of Arctic marine
29 organisms are clearly required.

30 The potentially severe

Percy, Grainger, Barry
Sergeant, Smith, Stein
In Chief

1 biological effects outlined above, are likely to have
2 relatively
3 /limited ecological significance in the wake of a single
4 oil spill during exploratory drilling, when considered
5 on a broad geographic scale. Far greater impact can
6 be anticipated from the cumulative effect of continuing
7 minor and major spills during the production and
8 transport of oil at multiple drilling sites. In the
9 broader ecological context the critical point will be
10 the relative balance between the accidental input of
11 oil on the one hand and the rate at which the oil is
12 removed from the environment by natural processes on
13 the other hand. Indications are that in Arctic seas,
14 the rate of input required to exceed the rate of
15 natural removal, will be considerably lower than in
16 temperate and tropical seas. In heavily exploited
17 regions, the imbalance between the two could lead to
18 oil concentrations over wide areas, approaching that
19 at which sublethal physiological and behavioral effects
20 are operative. Every effort should be made to obtain
21 theoretical estimates of the magnitude of such of these
22 factors, is input and elimination, under a variety of
23 conditions.

24 Since the only means of rigorously
25 testing such estimates is by monitoring an actual oil
26 spill, a detailed program should be prepared now to
27 intensively monitor the appropriate parameters in the
28 event of an oil spill during proposed exploratory
29 activities. Such information is essential for
30 anticipating the potentially more serious ecological
consequences of large scale production activity.

Percy, Grainger, Barry
Sergeant, Smith, STEin
In Chief

1 THE COMMISSIONER: Excuse me,
2 Dr. Percy. Can we get our terms straight? By "spill",
3 do you include a blowout?

4 A Yes.

5 Q You do? Well let me just
6 ask you this. If you did, if you carry out exploratory
7 drilling in the Beaufort SEa, you run the risk of a
8 blowout, which, I take it, is what you've been dealing
9 with principally, and of course you're concerned about
10 the enhanced risk, at least I take it that's what you
11 mean, if a large-scale program of exploration and
12 production is embarked upon, consequent upon the
13 building of a pipeline. We have heard that Foothills
14 wants to bring a 35,000-ton tanker with fuel oil into
15 Tuktoyaktuk Harbour, that's one of their proposals.
16 So that is one aspect of this whole project that might
17 give rise to a spill, and of course there is the
18 liklihood of a minor spill of fuel oil in so many ways;
19 handling, and so forth.

20 One thing you haven't mentioned
21 is that if you had a program of -- if you were producing --
22 if you found oil and gas, well let's say oil, if you
23 found oil in the Beaufort SEa and you were producing it,
24 you'd have flow lines coming in under, it would be
25 built under the sea bed, that seems to be the only way
26 you could do it. Now, I have assumed all along that
27 you were dealing with a blowout because that is uncon-
28 trolled, whereas a leak in a flowline presumably has
29 only a limited potential for spillage because you can
30 turn a valve at the wellhead and stop it, at least I

Percy, Granger, Barry
Sergeant, Smith, Stein
In Chief

1 assume you can. At any rate, when you talk about a
2 spill, you're really encompassing the whole range of
3 possibilities.

4 A Right. I think it's
5 generally true that, especially in temperate areas, the
6 general feeling is that more oil gets into the
7 environment through these various accidental small spills
8 here and there, rather than by these massive spills
9 that cause dramatic damage over relatively limited
10 areas, but more massive damage, and this is what I was
11 trying to get at. The long-term effects of these
12 sort of cumulative spills are probably going to be more
13 dramatic, or not more dramatic, but certainly more
14 ecologically -- have a greater ecological impact over
15 the long-term, over the broader area.

16 In addition, further studies
17 of sublethal physiological and behavioral effects are
18 required to determine the minimum concentrations of
19 oil in the environment that are sufficient to induce
20 significant sublethal dysfunction in ecologically
21 important species. Some of the behavioral effects
22 that I've mentioned so far, in our study, we've
23 indicated that they do occur, but we haven't yet pushed
24 the concentrations of oil down to the minimal levels
25 at which they occur, so we know nothing about this yet,
26 and this is a fairly important point. The studies
27 presented here are suggestive, but being of limited
28 duration and scope must be considered little more than
29 preliminary groundbreaking.

30 Short-term studies, no matter

Percy, Grainger, Barry
Sergeant, Smith, Stein
In Chief

1 how carefully executed, cannot be expected to adequately
2 fill the void resulting from years of neglect of basic
3 Arctic research., Arctic marine research in particular.
4 It is unfortunate that the pace and scope of present
5 attempts to fill this information void are more influenced
6 by developmental and economic considerations, than by
7 carefully considered scientific judgements.

8 THE COMMISSIONER: Excuse me
9 doctor, for a second. When you say, when you refer to
10 "short-term studies, no matter how carefully executed,"
11 the short-term studies you're speaking of, are you
12 referring to the Beaufort Sea study?

13 A Primarily, strictly impact
14 studies of that type, yes, which are, you know, which
15 are specifically oriented to a specific problem
16 without having the broader background information on
17 which to integrate the information from the short-term
18 studies.

19 Q Could I ask you this?
20 Dr. Grainger said that what is required is essentially
21 purely scientific examination of the marine life of
22 the Beaufort Sea, accumulation of a data base, and
23 then he said a second way of examining this thing would
24 be to have specific impact studies, I'm not doing
25 justice to his dichotomy but, was the Beaufort Sea
26 study essentially in the second category rather than
27 in the first?

28 A In its principal aspects
29 I would say, yes. Part of the problem is, as I pointed
30 out earlier, is that it's fine to do a lot of these

1 lab oriented type studies, where you're looking at
2 specific impacts on specific organisms; but then you've
3 got to go to the natural environment, and unless you've
4 got a good grasp of what's going on in the natural
5 environment, no matter how carefully these direct impact
6 studies have been done, you just can't fit them into
7 natural environment, and you can't determine what the
8 long-term effects are.

9 For example, we could show quite
10 readily, for example, that a specific species is very
11 sensitive to oil, and might be quite readily wiped out
12 by an oil spill; but what impact that would have on the
13 ecosystem as a whole, well I have no idea, because we
14 don't know what animals depend on that species, what
15 animals it feeds on, what it preys on this / We just
16 don't know what all the inter-relationships are, sort
17 of the basic structure of the ecosystem.

18 I've just indicated a few areas
19 of further research here that might be contemplated. To
20 attempt to outline important areas of additional study
21 is a formidable task, particularly in view of the fact
22 that little reliable information is available at present
23 without even the most basic ecology and physiology of the
24 great majority of Arctic marine invertebrate species.
25 However, specifically with reference to direct effects
26 of oil on marine ecosystems, the following work is
27 particularly important.

28 In view of its obvious
29 vulnerability to oil spills, we require further studies
30 on the species composition, general ecology, trophic

1 inter-relationships, and ecological importance of this
2 sub-ice community that Dr. Grainger and I have been
3 referring to off and on.

4 Secondly, further studies on
5 the interaction between spilled oil and suspended
6 sediments to better understand the rates of incorporation,
7 ecological impact, and the fate of crude oil in the
8 bottom sediments. This is being done to a certain
9 extent for temperate waters, but certainly nothing has
10 been attempted in Arctic waters at the moment.

11 Thirdly, studies of lethal and
12 sublethal effects of crude oils on major Arctic
13 zooplankton species and particularly on larval stages,
14 about which we know very little., as far as crude oil
15 impacts are concerned.

16 Fourthly, further studies on
17 sublethal physiological and behavioral effect to
18 obtain realistic estimates of the minimum concentrations
19 of crude oil, at which demonstrable disruption of
20 physiological functioning occurs, particularly following
21 extended exposure to the pollutant. Such estimates
22 of biologically critical concentrations will be
23 particularly useful in conjunction with item number 5.

24 And item number 5 includes
25 studies on the time course of detoxification and the
26 elimination of spilled oil from Arctic marine ecosystems
27 in order to evaluate the relative balance between the
28 potential rate of input and the capacity of the system
29 to cleanse itself. This is, of course, particularly
30 important in relation to item 4, where we can

Percy, Grainger, Barry
Sergeant ,Smith, Stein
In Chief

1 demonstrate levels at which significant biological
2 effects occur, but there is still not too much infor-
3 mation about how readily these levels might build up
4 in the Arctic marine ecosystem.

5 THE COMMISSIONER: Dr. Pimlott
6 in his presentation referred to Alaska and, if I can
7 find it, said that -- I probably can't find it -- but
8 he referred to the work being done in Alaska and I
9 -- it's in there somewhere, I'll find it after lunch --
10 but we share this Arctic Ocean with Russia , the
11 United States and the Scandanavian countries^{and} Denmark,
12 I guess, and I was wondering if any of you -- and you
13 can comment on this after lunch at the appropriate
14 time, or perhaps Dr. Millen could, Mr. Bayly. You
15 people were carrying out this program, this 2-year
16 program which had some deficiencies -- not deficiencies
17 but inherent shortcomings -- and what about the
18 Americans and Russians, have they carried out similar
19 programs? Are they contemplating deep water^{drilling} off-
20 shore? Are they concerned about the problems of oil
21 spills in these northern waters? Have they been tackling
22 similar problems, and if so, has it been done as you
23 say, on the impetus being provided by developmental
24 considerations rather than scientific considerations?

25 A Well, certainly there
26 is a comparable program going on at present in Alaska,
27 comparable to the Beaufort Sea program. It started^{as},
28 I think, the Canadian Beaufort Sea program was winding
29 down, and from the proposals and programs I've seen
30 it seems to complement the Canadian Beaufort Sea program.

Percy, Grainger, Barry
Sergeant, Smith, Stein
In Chief

1 it covers certain areas that we have covered only in
2 American waters, and it's basically a complementary
3 program to the Beaufort Sea program and it is going on
4 at present, and is being allowed to continue for, I
5 think, about three years altogether.

6 The Russians have certainly
7 had a considerable interest in the effects of oil on
8 Arctic organisms. I can't speak too much as to exactly
9 what the main regulating factors of this research have
10 been but I know they have had fairly intensive research
11 on the effects of oil on marine organisms in both
12 temperate and Arctic waters.

13 THE COMMISSIONER: What time
14 is it?

15 MR. GOUDGE: Would it be
16 appropriate to break for lunch, sir? It's 12:30.

17 THE COMMISSIONER: We'll adjourn
18 till two.

19 (PROCEEDINGS ADJOURNED AT 12:30 P.M.)

(PROCEEDINGS RESUMED PURSUANT TO ADJOURNMENT)

THE COMMISSIONER: Well, we
will come to order ladies and gentlemen.

MR. BAYLY: Dr. Percy had a
comment or two on the American program and he would
like to deal with that now.

WITNESS PERCY: It has been
brought to my attention that I said that the program
was three years long, but in fact it is four to five
years, the overall program there, now I'm embarking
on slightly longer --

THE COMMISSIONER: Excuse me,
the American program in the Beaufort Sea is four to
five years long, and it is just now getting under way.

A It's not just the Beaufort
Sea, it includes the Beaufort Sea, Chukchi Sea, the
Bering Sea and the Gulf of Alaska.

Q
Have they been engaged in exploratory drilling, exploratory wells,
in the Beaufort Sea, either near the shore or in deep
water?

A I couldn't really answer
that, I don't think there have been any exploratory
drilling off Prudhoe Bay, in the Beaufort Sea area.

A Perhaps then we could
go to the evidence of Mr. Stein.

WITNESS STEIN: It should
be apparent here, Mr. Commissioner, that the testimony
that I am presenting, I have actually attempted here to
take more or less a general look at industrial
development activities in the delta region, in its

Percy, Grainger, Barry
Sergeant, Smith, Stein
in chief

entirety, and I haven't restricted myself to strictly offshore explorations.

The Fisheries Marine Service, Western Region, initiated studies of the Mackenzie Delta as part of the Environmental-Social Committee's Mackenzie Valley Pipeline Program. From a base camp located in Aklavik, between 1972 and 1974, field crews examined the fish resources over much of the southern reaches of the Delta, the main objectives being to:

One; define the biology and life histories of the major fish species including age composition, growth rates, species composition, distribution and food habits.

Two; determine the timing of fish migrations and the major migratory routes used.

Three; to locate and define critical habitat areas, including areas utilized for spawning, rearing, feeding and overwintering purposes.

Four; identify areas normally fished domestically and obtain an estimate of the quantities of fish taken.

The project results have been presented in a series of reports to the Environmental-Social Committee, and are listed as an appendix to this statement.

During 1974, a study of the anadromous and freshwater fish of the outer Mackenzie Delta was initiated under the auspices of the Beaufort Sea Project. In addition to expanding on the objectives

Percy, Grainger, Barry
Sergeant, ~~Smith~~ Stein
In Chief

1 given previously, the Beaufort Sea Study also attempted
2 to:

3 One; establish the seasonal
4 and geographic sensitivity of the fish resources, and
5 two; to examine lagoons subject to inundation from
6 the Beaufort Sea, and ascertain their role in the life
7 histories of major species.

8 A series of approximately 75
9 locations were sampled during the field season. Four
10 of these were considered as monitoring sites and were
11 sampled once a week. Results of the Beaufort Sea
12 Study have been presented in two reports by Percy and
13 others--Beaufort Sea Project B-2, and ^{Percy}/Beaufort Sea
14 Technical Report No. 8. Additional Fisheries projects
15 conducted under the Beaufort Sea Program included
16 studies of the Yukon coastal region by Kendel and
17 others-- '76, Beaufort Sea Project Technical Report
18 No. 6 -- and an investigation of the eastern Beaufort
19 Sea by Galbraith and Hunter -- Beaufort SEa Project
20 Technical Report No. 7.

21 Deltas in general represent
22 some of the most productive ecological systems in the
23 world. They represent important habitats wherever they
24 occur, but are especially important in the north where
25 alternative productive habitat often does not exist in
26 the surrounding region. In the case of the Mackenzie
27 Delta, many of the freshwater species of the southern
28 Beaufort SEa and Mackenzie River system depend on the
29 delta. Several marine species also frequent the outer
30 delta.

Freshwater fish populations in the delta region can be placed in one of two rather general categories. This first of these, anadromous fish, includes such species as humpback and broad whitefish, Arctic and least cisco, inconnu and Arctic char, which spend much of their life cycles in brackish or marine waters while migrating into fresh water to spawn or over-winter. These spawning migrations may begin as early as July one -- I'm sorry, as late July, with the adults usually completing the return migration by November. While some species, such as inconnu and Arctic cisco, appear to migrate as far upstream as Norman Well, others, such as broad and humpback whitefish, apparently utilize back eddies of the Mackenzie River, the delta itself, or more southerly tributaries such as the Arctic Red and Peel Rivers.

The second category might be called resident species or populations which spend their entire life cycle in freshwater and are only rarely encountered in the marine environment. This group includes such species as northern pike, Arctic grayling, and suckers. Although migrations may be made, the spawning habitats are usually local.

Marine species, such as saffron cod, starry flounder and Arctic flounder normally reside in salt water. However they are frequently found in the brackish water of the inshore delta, presumably to feed. Additional species are also found farther offshore with ARctic cod being most abundant.

The delta region provides

Percy, Grainger, Barry
Sergeant, Smith, Stein
in Chief

1 essential habitat for a multitude of fish species. The
2 Beaufort Sea study alone identified at least 19 species
3 of freshwater fish and 4 marine species inhabiting the
4 outer delta. Some species such as the Arctic cisco,
5 feed heavily during the spring and early summer months
6 prior to beginning spawning migrations. Once migration
7 begins, it appears that feeding essentially ceases until
8 the completion of spawning. Of course certain areas
9 of the delta and Beaufort Sea seem to be more important
10 than others for feeding purposes. This is especially
11 true of coastal lagoons or ~~lakes having outlets to delta~~
12 channels or the sea. Clear deep lakes on the other hand
13 are primarily used by lake trout and least cisco. Coastal
14 lagoons also appear to be important nursery areas for
15 anadromous species, the juveniles having moved down
16 from spawning areas during the spring freshet.

17 Although spawning is known to
18 occur within the delta itself, few specific areas have
19 been identified. Resident populations probably make
20 use of smaller lakes and channels or streams such as
21 Holmes Creek. Populations of humpback and broad
22 whitefish are thought to make use of backeddies within
23 the delta, or the Mackenzie River itself. However, for
24 most migratory populations the delta serves only as
25 a migration route to upstream spawning areas.

26 Much of the delta and inshore
27 Beaufort Sea also provide overwintering habitat for
28 marine, resident and migratory populations. Lakes and
29 channels with sufficient depth are utilized by whitefish,
30 least cisco and lake trout. Least cisco, Arctic cisco,

1 Arcitic flounder, burbot, boreal smelt, inconnu and
2 fourhorn sculpin overwinter in Mallik Bay. Areas
3 suitable for overwintering are also plentiful along the
4 northeast coast of Richards Island. Relatively small
5 numbers of boreal smelt, humpback whitefish and least
6 cisco have been netted through the ice in Kugmallit Bay,
7 but this is probably a reflection of low fishing effort,
8 in winter. Inconnu and fourhorn sculpin have also
9 been captured in the Shingle Point area, west of the
10 delta, in winter.

11 Because of the abundant and
12 diversified habitats available, the abundance of the
13 fish resource itself and the use made of that resource,
14 the Mackenzie Delta has been designated by Fisheries
15 and Marine Service as an area likely to be sensitive
16 to pipeline construction. There are several aspects
17 of pipelining which are expected to adversely affect
18 the aquatic resources. These include gravel removal,
19 water use, increased sedimentation, road construction,
20 increased fishing pressure and the use of methanol for
21 pipeline testing. In previous testimony before this
22 Commission, I discussed these concerns in some detail,
23 and provided recommendations which, in my opinion, will
24 reduce adverse effects to acceptable levels. These
25 appear in Volume 103 of the Proceedings Pages 15720 to
26 15743. I only wish to point out here that these
27 concerns and recommendations are equally applicable, if
28 not more so, to the delta region as to the rest of the
29 Mackenzie Valley.

30 However, there are other

Percy Grainger, Barry
 Sergeant, Smith, Stein
 In Chief

development plans which could result in greater disruption to the resource than that associated with what might be called normal pipelining activities. Dredging for instance is proposed for the construction of major delta channel crossings and may also be required for development of medium draft harbour facilities for drill ships or to improve access to wharves and stockpile sites. Although such operations are normally of concern because of the environmental effects of increased levels of suspended sediment, they are of particular concern in an area inhabited by so many migratory fish populations. Dredging operations will likely be conducted during periods of mass fish migration but, in my opinion, we do not possess the predictive capability to speculate on how these migrations will react to multifold increases in normal suspended sediment levels, the mechanical noises of the dredging operation itself, or to changes in flow patterns either over the spoil pile or around berms constructed to facilitate dredging. These concerns could be mitigated by timing dredging operations to avoid critical migration periods. However care must also be taken to avoid interference with other resources such as the beluga whale.

Seismic exploration in the delta and Beaufort Sea region has increased sharply over the past few years and can be expected to continue for some time to come. Such techniques will be used to delineate gas and oil fields, determine the extent of permafrost layers and ascertain where abnormal

Gray, Gearing, Barry
 elegant, Smith, Stein
 u Chiet

pressures may be encountered. Unfortunately, there is limited information available on how such techniques affect northern fish species. High explosives as well as air guns are currently in use, and while the former provides the best geological information, it is also the most destructive to the fish resource, including all the domestically and commercially important species. Mortality, especially, results with those species with gas bladders since they are unable to adjust to rapid pressure changes. Until better information is available, we can only recommend that seismic operations avoid known critical habitat areas and be conducted during times considered least sensitive to the resource.

The potential for disruption of aquatic environments can be expected to increase significantly during the exploratory drilling phase of delta development. One area of concern is the disposal of wastes and drilling fluids which are used in large quantities to equalize hydrostatic pressures, to remove drill cuttings and to lubricate the drill bit. They usually consist of a water-clay mixture, although many chemicals are added to the muds for viscosity improvement, pH adjustment, anti-corrosive properties, weight and a host of other desirable factors for drilling.

Drilling fluids from the Mackenzie Delta and nearshore Beaufort Sea have been shown in a number of studies to be acutely toxic to fish in freshwater, and more recently to both fish and

Percy, Grainger, Barry
Sergeant, Smith, Stein
In Chief

1 intertidal invertebrates in marine waters. In normal
2 land-based drilling, drilling fluids, brines and
3 cuttings, along with "house-keeping wastes", are
4 contained for extended periods in earthen sumps and
5 treated to render them innocuous. However, this
6 procedure will not be feasible in offshore drilling
7 where space will be a limiting factor. Since the
8 composition of drilling fluids varies widely from well
9 to well and within a single well, the toxicity to
10 aquatic fauna is also quite variable. It is imperative
11 therefore that there be stringent waste water and
12 drilling fluid disposal regulations, and enforcement
13 of those regulations.

14 The most obvious potential
15 threat to the aquatic environment associated with
16 proposed offshore exploration is a massive oil spill.
17 Although fish gills are mucous coated, effectively
18 repelling minute quantities of oil, they are incapable
19 of accommodating a major polluting incident. If gills
20 become oil-coated, respiration and ion exchange are
21 severely limited. This ultimately leads to death since
22 there is no self-cleaning mechanism. Fish are more
23 likely to come into intimate contact with oil in
24 a dispersed form, rather than floating slicks; moreover,
25 oil in emulsion appears to adhere to gill tissue more
26 readily. Solution of the lighter saturated and aromatic
27 components of oil, also the most toxic to fish, in the
28 water column occurs early in the life of an oil slick.
29 An offshore spill would therefore tend to lose its
30 toxic components before reaching the nearshore zone.

Percy, Grainger, Barry
Sergeant, Smith, Stein
In Chief

1 However, recent evidence suggests that oil can be
2 incorporated into newly forming ice, thus rendering the
3 weathering and biodegradation processes inoperative for
4 extended periods; and I think reference was made on
5 several occasions to this factor this morning.

6 Pollutants such as oil, also
7 can cause nervous and gastric disorders in fish. Fish
8 of different species, size and age vary in their
9 resistance to pollutants. Physiological and behavioural
10 changes brought about by pollutants will interfere with
11 the ability of fish to cope with the "normal" stresses
12 in an already harsh environment. There is a definite
13 need to examine the sublethal effects of pollutants on
14 aquatic organisms. The presence of even small quantities
15 of petroleum hydrocarbons, in the flesh of fish can also
16 produce disagreeable flavour and odours. This is an
17 important aspect considering the domestic utilization of
18 the resource in the southern Beaufort Sea.

19 Most likely however, impact on
20 the fish resource itself resulting from an oil spill
21 will be through large-scale loss of food organisms,
22 probably resulting either from a change of food habits,
23 or in a change in food habits, or emigration from the
24 contaminated area. Sinking readily takes place --

25 THE COMMISSIONER: Excuse me,
26 Mr. Stein. What is it that you want to say there,
27 "probably resulting either from a change in food habits"?

28 A I think that was possibly
29 a typing error, sir. I believe it should read that
30 probably resulting either in a change in food habits of

Tercy Greinger, Barry
 Sergeant, Smith, Stein
 In Chief

1 the fish themselves, or else emigration from the
 2 contaminated area.

3
 4 Sinking readily takes place
 5 in estuarine loations since suspended sediments are
 6 available as adsorptive nuclei for oil. The benthic
 7 flora and fauna upon which many fish species depend,
 8 may, as a result, be reduced or contaminated for
 9 extended period~~s~~. Free oil and emulsions can also
 10 coat algae and other plankton, causing them to settle
 11 to the bottom, out of reach of pelagic fishes.

12 Any large scale reduction in
 13 the aquatic invertebrate fauna would have a profound
 14 effect on the fishery. Stomach analysis indicate that
 15 fish utilizing the area are largely dependent on this
 16 fish resource, on this food resource, sorry. Many of the
 17 fish species present tend to be opportunists in their
 18 feeding habits and could therefore probably compensate
 19 for minor changes. It should be noted that all species
 20 are important to the stability of an ecosystem, since
 21 the more diverse the biological community, the greater
 22 its ability to compensate for changes in the environment.

23 SEveral coastal areas near the
 24 Mackenzie Delta contain fish populations which may be
 25 sensitive to contaminants originating offshore. It
 26 appears that many of these lagoons and embayments are
 27 not normally flushed by the Mackenzie. Low rates of
 28 exchange of water and the occurrence of storm tides
 29 therefore render these areas highly susceptible to
 30 pollutant contamination from routine exploration
 activities or to oil from an uncontrolled well blowout.

Percy, Grainger, Barry
Sergeant, Smith, Stein
In Chief

Areas sensitive to disruption are found along the west coast of Tuktoyaktuk Peninsula, the irregular coast, I'm sorry, northeast shoreline of Richards Island between Pullen and Hendrickson Islands, the Mallik Bay area on the north shore, and the Yukon coast. All contain large populations of adults and fry throughout the summer months, primarily whitefish, ciscos and inconnu. These habitats provide a haven within the Beaufort Sea/delta area for marine species such as flounders, sculpins, pacific herring and saffron cod. Fish also concentrate near Kendall Island, least cisco and burbot; and Garry Island, boreal smelt and ciscos, during the summer. These areas become even more sensitive in fall, at which time inconnu congregate for overwintering in nearby channels and in Mallik Bay. With the exception of the western and northwestern portion of Shallow Bay; which is a migration corridor for char, inconnu and ciscos, no large fish populations were found in the region between Shallow Bay and Garry Island during our Beaufort Sea investigations.

Should a massive polluting event occur offshore of the delta, it is imperative that the polluting material be prevented from reaching critical inshore habitats. In my opinion, mechanical clean-up techniques alone should be used in combating oil spills until we have gained a greater insight into the fate and effects of dispersants and of dispersed oil in the marine environment. Often, the emulsifiers that are used in temperate waters prove to be more toxic to fish than the oil being mopped up. Similarly, sinking

Percy, Grainger, Barry
Sergeant, Smith, STein
In Chief

1 agents merely transfer the problem from the surface to
2 the bottom where it becomes virtually impossible to deal
3 with. Mechanical clean-up equipment now in use must
4 be radically improved to cope with oil spills at
5 sea and new approaches devised to recover oil on and
6 under ice. It is recommended that during any polluting
7 incident first priority be given to preventing oil or
8 other pollutants from moving into the nearshore zone
9 where contact with estuarine waters will lead to its
10 sedimentation and retention for extended periods of
11 time. Sedimentation of oils and tars along the coast
12 could destroy nursery and spawning areas and may kill
13 essential benthic food organisms or force them to
14 emigrate from the area.

15 If approval is granted for
16 offshore exploration, an essential requirement is a
17 program of effective resource monitoring studies that
18 will facilitate the identification and resolution of
19 potentially dangerous environmental problems at the
20 earliest possible stage. Studies done to date are not
21 adequate to predict the effects of extensive offshore
22 drilling and production in the Beaufort Sea. It is
23 important that further studies be carried out prior to
24 such development, during the period of disturbance and
25 during an assessment phase. It is critical to monitor
26 control zones, along-side impacted areas, in order to
27 distinguish natural environmental trends from those
28 changes induced by man. Now that an inventory of base-
29 line data for environmental components in the Beaufort
30 Sea has been compiled, adequate oil clean-up contingency

Percy, Grainger, Barry
Sergeant, Smith, Stein
In Chief

1 plans can and must be developed. These must not be
2 imported from other less hazardous areas in the south,
3 but be developed with the specific environmental
4 problems of the area as a focus.

5 It is my understanding that
6 baseline hydrocarbon levels in tissues of a few species
7 of plankton, invertebrates and fish, as well as for
8 Beaufort Sea water have been determined. The report is
9 not yet available. This program should be expanded to
10 provide reference material for comparison with
11 hydrocarbons found in tissues and water at later dates.
12 This will be particularly useful in determining the
13 persistence of oil in the Arctic aquatic environments.
14 Industry should provide samples of oil discovered in
15 the Beaufort Sea area to allow meaningful site-specific
16 toxicity and behavioral studies to be carried out.

17 In conclusion, the Mackenzie
18 River Delta provides essential habitat for the
19 maintenance of the freshwater, coastal marine and
20 anadromous fish resources in much of the southern
21 Beaufort Sea area and Lower Mackenzie River. The inshore
22 zone is an important nursery, feeding and overwintering
23 site for both nearshore and offshore organisms. It is
24 especially important to those anadromous species which
25 form the basis of the domestic and commercial fishery
26 in the Delta, that is broad whitefish, Arctic char,
27 Arcti cisco, and inconnu. Standing stocks of fish are
28 greatest nearshore since the anadromous species tend to
29 frequent shallow coastal waters during the summer
30 months rather than moving far offshore.

Percy, Grainger, Barry
Sergeant, Smith, Stein
In Chief

1 Proposed developments in the delta region can be expected
2 to adversely affect aquatic resources. In my opinion,
3 only if industrial developments incorporate environmental
4 design measures, as recommended to this Commission, will
5 these effects be minimized.

6 THE COMMISSIONER: One question
7 Mr. Stein. On page 10, you say about seven lines down,

8 "Now that an inventory of baseline data for
9 environmental components in the Beaufort Sea
10 has been compiled, adequate oil clean-up
11 contingency plans can and must be developed."

12 The impression I got from Dr. Grainger and Dr. Percy
13 was that, that wasn't something that they could say
14 about the fields of their expertise. Limiting yourself
15 to these fish species, well let me put it this way,
16 are you limiting yourself to these fish species, or
17 am I to take a larger meaning from what you've said
18 there?

19 A I would say that primarily
20 I would limit myself to fish, but I think that what I
21 was really getting at was, I think if we were to take
22 a poll of the panel sitting here, I'm sure that we would
23 all agree that we do not have as much information as
24 we would like, but the -- as I see it right now, we
25 have at least a preliminary feeling for what is there,
26 where they are, what the abundance of the fish species is.

27 Q What you're saying is
28 that you know enough to decide that your first priority
29 would be, if there were an oil spill in the Beaufort
30 Sea, to keep the oil by any means away from the inshore area.

Percy, Grainger, Barry
Sergeant, Smith, Stein
In Chief

1 A That's correct. I think
2 that we've got enough now, and looking towards the
3 future and the likelihood of increasing our knowledge,
4 I think that it's imperative that we start planning on
5 the basis of what we have, at least, and modify
6 accordingly.

THE COMMISSIONER: Thank you.

7 MR. BAYLY: I wonder if
8 we could go now to Dr. Barry's evidence, and Dr. Barry
9 could you read your evidence before the Inquiry?

10 WITNESS BARRY: Yes. First I
11 must apologize for the condition of this report. It
12 is typed from a garbled tape and I didn't discover it
13 until just the other day, and make any corrections, so
14 I'll attempt to paraphrase in spots.

15 Birds found in the Beaufort
16 Sea region converge from wintering grounds in the
17 Pacific and Antarctic Oceans and from North and South
18 America. That is about a third of the surface of the
19 globe. Of the birds nesting on the Coast of the
20 Beaufort Sea and the Arctic Islands, approximately
21 two-thirds migrate through the Great Plains and the
22 Mackenzie Valley, while the rest travel through the
23 Bering Straits and follow the coast of Alaska, Yukon,
24 and the Northwest Territories.

25 Water birds moving along the
26 narrow leads, which usually form between the shore-fast
27 ice and the Arctic pack in May and June, can become
28 extremely concentrated under certain conditions. Species
29 using the Arctic coast migration route include Arctic
30 terns, Sabines gulls, jaegers, all coming from the

Percy, Grainger, Barry
 Sergeant, Smith, Stein
 In Chief

1 Antarctic and South Pacific. Pacific brant from
 2 coastal Mexico and California, and murres and eiders and
 3 glaucous gulls from the North Pacific and Bering Sea.
 4 Some species flying the interior migration routes also
 5 use the coast, especially the whistling swans, which
 6 move westward in the spring from the Mackenzie Delta
 7 and travel along the Yukon and Alaskan coasts.
 8 Many of the snow geese follow the coast of the
 9 Tuktoyaktuk Peninsula while enroute from the Mackenzie
 10 Delta to Banks Island and they also use these
 11 same routes again in the fall, there's almost a
 12 duplication.

13 The Beaufort Sea is very shallow
 14 near the Coast. The ten-fathom contour line is about
 15 20 to 25 miles offshore. Tidal changes are only
 16 between one and two feet, but onshore winds can often
 17 cause storm tides of up to eight feet during the ice-
 18 free periods. The polar pack ice may completely cover
 19 the Beaufort Sea in any season. Typically, however,
 20 an ice-free margin extending from three to one hundred
 21 or more miles offshore exists at least intermittently
 22 between early July and late September.

23 The discoveries of oil and
 24 gas along the rim of the Beaufort Sea and the
 25 prospective offshore drilling has shown the need for
 26 more reliable information about the marine avifauna.
 27 In the past, population estimates of Beaufort Sea birds
 28 were from casual surveys conducted as part of other
 29 studies or reconnaissances. From work done in the
 30 past several years, we estimate that there are

Percy, Grainger, Barry
Sergeant, Smith, Stein
In Chief

1 approximately 2,000,000 migratory birds that frequent
2 the Beaufort Sea and the littoral zone; by the littoral
3 zone, I mean the area up to the highest of storm tides.
4 There are several species of water birds, for which
5 the shores and marshes are the principal nesting
6 grounds. For large numbers of seabirds, the coastal
7 bays, the lagoons, the barrier beaches and the islands
8 are important as nesting and for molting. For seabirds
9 migrating along the coast, the open water leads in the
10 sea ice are the traditional places for resting and
11 feeding. Open water leads form along the Coast and
12 allow a migration route, which the birds follow, and
13 it's become quite traditional, it occurs almost every
14 year. To reduce the risk of contaminating these birds
15 by an oil spill or a blowout, it is important to know
16 the critical times and places for the birds found in
17 the Beaufort Sea. Such information about the avifauna
18 makes possible the timing and location of drilling
19 and support activities in order to minimize the danger.

20 The data presented here
21 concerning the spatial and temporal distribution of
22 birds in the Beaufort Sea results from three different
23 methods of doing surveys: regular ground surveys where
24 you sit and watch them migrate over us, aerial surveys,
25 and more recently, radar observations. However, it is
26 difficult to estimate the numbers of migratory birds
27 because of difficulties of weather conditions,
28 difficulties of visibility and because it's an ever-
29 changing, mobile population. Nevertheless, it might be
30 useful to make a few estimates of some of the more

Percy, Grainger, Barry
Sergeant, Smith, Stein
In Chief

important birds. There are at least three species of loons that are normally seen in the Beaufort Sea, and our estimate is that approximately 35,000 of these birds will pass through the Beaufort Sea at any one season. There are three different species of jaegers that migrate through the Beaufort Sea. Our estimate is 21,000. The largest gull in the area, the glaucous gull, we estimate at about 35,000. The old squaw duck, or squaw duck, is a very common bird in the Arctic, and approximately 1,130,000 are estimated to migrate through the Beaufort Sea. There are two species of eider ducks, which we lump together for some reasons of difficulty of identification, and we estimate at about 1,100,000 are found in the Beaufort Sea area. Whitefronted goose, whitefronted geese use mostly the coastal areas on the mainland, approximately 25,000 are estimated to occur in the Liverpool Bay area, and includes Eskimo Lakes. There are at least 200,000 snowgeese nesting on Banks Island and many of them follow the shores at Tuk Peninsula enroute to Banks Island. There are approximately 25,000 to 30,000 Pacific brant migrating along the coasts of the Beaufort Sea, also there are uncounted thousands of shore birds: plovers, turnstones, sandpipers, and so forth.

I will digress a bit here to mention the radar studies that we had conducted last May and June from Komakuk Beach near the Alaska border. We found that above the normal range of visibility, there were birds migrating through at elevations up as high, in some instances as high as 16,000 feet. Where their

Percy, Grainger, Barry
Sergeant, Smith, Stein
In Chief

1 destinations were, and exactly how many were involved,
2 is very difficult to see, because all we're getting
3 were radar blips of birds coming over the mountains
4 and from several different directions. Their total
5 number and their destination we don't know, but this
6 would be added to these estimates that we're making.

7 During our ground, aerial and
8 radar surveys conducted in the years 1972 through
9 1975, we covered the coastal lagoons and the shorelines,
10 and as far out to sea as 200 miles; in other words the
11 southern part of the Beaufort Sea. This coverage to
12 200 miles offshore, covers approximately the same area
13 the Federal Oil leases for exploration and development
14 of oil have been made. It's a bit astounding that there
15 are oil leases quite far out to sea.

16 As a result of all these
17 surveys, we found that as far as birdlife was concerned,
18 that there are sensitive areas and times for their
19 occurrence in the Beaufort Sea. The most important
20 are the ice leads, those areas of open water that form
21 between the shorefast ice and the Arctic pack in the
22 early spring. The leads are a migration route for
23 some species like eider ducks, old squaws, and loons,
24 where they have a place to stop either to rest or to
25 feed during their migrations. During the fall
26 migration, the ice has usually retreated to the north.
27 There are large areas of open water. The ice leads
28 are important only during the spring migration which
29 occurs around the first of May to early June. Some
30 migration actually begins in April. ..

Percy, Grainger, Barry
Sergeant, Smith, Stein
In Chief

1 The aspect that makes the ice
2 lead so sensitive is the fact that a sea bird may be
3 flying for literally hundreds ^{or even thousands} of miles over ice before
4 it finds anything that even looks like water. There
5 are traditional places such as off Cape Dalhousie, and
6 earlier off Cape Perry, where
7 almost invariably be open water in early spring. These
8 birds will concentrate there because it is the only
9 place where they can land, they have to land on water.
10 Some species, like loons, are incapable of taking off
11 from land, so they're absolutely helpless unless they
12 can land on water.

13 We have found in our flights
14 that as many as 75,000 to 100,000 eider ducks and other
15 diving ducks can be concentrated at these spots, like
16 off Cape Dalhousie, at any one time. This is a
17 transient population, that might be there one day and
18 could be replaced by another large group the next day or
19 week, as the birds continue moving along to their
20 nesting grounds. The attractiveness of the first open
21 water to appear in the spring can be demonstrated by a
22 photograph which I'll pass around. This photograph was
23 taken about twenty years ago, in 1957 or 1958 by a
24 bush pilot at Norman Wells. There was an oil spill on
25 top of the ice early in that year. It looked like
26 water, and the first arriving ducks and geese therefore
27 found it as the place to land. The attractiveness of
28 openwater to first-arriving birds is true, not only
29 along the coast, but also along the Mackenzie River in
30 the pre-breakup stage. You will note that this picture

Percy, Grainger, Barry
Sergeant, Smith, Stein
In Chief

1 and it looks like water, is nothing but a large pool
2 of oil. In the course of a few days over 400 migrati
3 geese, swans and ducks were trapped. The second
4 photograph shows the condition of these birds. They
5 were of course completely wiped out. So this is one
6 sensitive and important area: the first-appearing
7 open water in the spring, in this case the leads along
8 the Arctic Coast.

9 The other sensitive areas for
10 migratory birds in the Beaufort Sea are the coastal
11 lagoons, and bays and barrier beaches and the tidal
12 marshes from June through late September, and even
13 actually into October and to freezeup. The barrier
14 beaches and the coastal areas and the tidal marshes
15 are important for several reasons. It is the rearing
16 area for birds that nest either on the marshes or on
17 the periphery of these areas. The young are frequently
18 taken to the water where they feed and develop. It
19 is also a moulting ground -- all ducks, geese and swans,
20 by the way, moult in the summertime, and by that they
21 lose all their flight feathers and become completely
22 helpless.

23 For protection, large flocks
24 get into the bays and lagoons and become flightless
25 for a period of 30 to 45 days, depending on the species.
26 These birds are absolutely helpless. They are unable
27 to fly and any oil spill or contamination of these
28 barrier beaches or the lagoons will result in the
29 destruction of whole flocks. They flock up together
30 for protection, so they're usually quite concentrated.

Percy, Grainger, Barry
Sergeant Smith, Stein
In Chief

Later on in the fall, from August through September, the coastal marshes and the barrier beaches are staging areas. For instance, snow geese from Banks Island will migrate to the mainland coast, where the season is a bit more delayed, and they are able to feed and gain body weight and strength of flight, or strength in wing for the long migration south. These fall staging areas, especially the outer part of the Mackenzie Delta, and along the north coast of the Yukon and the Tuk Peninsula, are important to snow geese, whitefronted geese, brant, and many ducks.

There are about 100 different species of birds which use the Beaufort Sea or its littoral zone, sometime during any particular season. It is impossible to generalize about any one of them and their propensity for being involved in an oil spill, or a coastal pollution. It would be confusing to try to go through the life histories of all these different species. I think the best way would be to take several representative species of some of the more economically important and trace their occurrences in the Beaufort Sea at any particular season; and try to pinpoint areas that are liable to be critical, should an oil spill occur.

Probably the most valuable species in the Mackenzie Delta and the Beaufort Sea region is the lesser snow goose. Snow geese arrive in the spring by way of the Mackenzie Valley, stopping at various places, especially along the river where the first open water occurs. I mentioned earlier - the photograph at Norman Wells.

Percy, Grainger, Barry,
Sergeant, Smith, Stein
In Chief

1 This is one of the areas where if there appears to be
2 open water, the geese will stop. They move north
3 through the latter part of May and to the outer part of
4 the Mackenzie Delta. Many follow the main channel of
5 the Mackenzie, and ^{then} to Kitigazuit and along the Tuk
6 Peninsula to Banks Island.

7 In this area snow geese are an
8 important species, a food source, for the residents of
9 Tuktoyaktuk. They arrive at Banks Island in the latter
10 part of May, and begin nesting by the first of June.
11 Approximately 200,000 snow geese nest on Banks Island.
12 The nesting grounds are inland from the coast, and
13 Banks Island is what we call the main colony, and there
14 are two satellite colonies, or subcolonies: one of them
15 is at the Anderson River Delta, and the other is the
16 Kendall Island area in the central part of the Mackenzie
17 Delta. Both of these areas are low and are subjected
18 to spring floods and in the fall are subjected to
19 storm tides. The storm tides in the fall could carry
20 oil well onto the flats. As we mentioned before, storm
21 tides of six to eight feet can occur, depending on how
22 strong the wind is.

23 After the young hatch, the
24 snowgeese, they disburse on foot and moult on the
25 various river islands of both the Anderson River, the
26 Kendall Island area, and on Banks Island. When the
27 young are approximately four weeks old, and are able
28 to fly, they begin to accumulate into flocks ready for
29 migration to the staging areas. The fall staging areas
30 for snowgeese are the Mackenzie Delta westward into

Ferry, Granger, Barry,
Degeant, Smith, Stein
11-11-55

1 Alaska, and in some years on Bathurst Peninsula. Geese
2 are grazing birds, feeding to a large extent on the
3 grasses and sedges of the low flats of the Mackenzie
4 Delta, although they also go upland into the slopes of
5 the Yukon and Alaska. This particular area in the fall
6 is very sensitive. A storm tide could carry any large
7 spill onto the land. If the geese are disturbed or
8 if their food supply is destroyed by residue of oil
9 entrapped on the flats, it would just about eliminate
10 their ability to gain enough weight to continue their
11 migration. When the snow geese leave this area, they
12 have to put on, usually gain about one pound in the course
13 of twenty to thirty days, in the outer part of the
14 Mackenzie Delta, and if they are in good physical shape,
15 they are able to overfly the taiga, all the way into
16 the northern parts of Alberta, or in central parts of
17 the prairie, which is their next source of food. Very
18 rarely do they stop along the Mackenzie River, or on the
19 lakes on the way south.

20 Other species representative
21 of the Beaufort Sea are the eiders, both the king and
22 the common. They winter in the Bering Sea in the North
23 Pacific and in early spring, especially the males first,
24 follow the ice leads around the coast of Alaska and
25 along through the Beaufort Sea to nesting grounds,
26 located in the Arctic Islands and along the coast as far
27 east as Queen Maud Gulf. The migration route is a
28 traditional one that follows the open leads that are
29 expected to be found along the coast.

30 These leads are present more

Percy, Grainger, Barry,
Sergeant, Smith Stein
In Chief

1 years than they are not; but on occasion, as in 1964,
2 strong onshore winds prevented the leads from opening
3 up. We found eider ducks scattered along the coast all
4 the way from Prince Patrick Island, Holman Island,
5 Sachs Harbour, the complete Tuktoyaktuk Peninsula, all
6 the way to Point Barrow in Alaska. This was an unusual
7 situation in which no open water was available until
8 the end of June, after migration was over. In 1964,
9 we estimated approximately 100,000 eider ducks died of
10 starvation as a result of the fact that the leads did
11 not open up.

12 Now, it might be safe to assume
13 that if the leads were open, or if there was anything
14 in the leads that looked like open water, the eiders
15 would land in it. In fact there was a small piece of
16 open water in the fingers of the Eskimo Lakes, near
17 Saunatuk, which is not on the normal migration route,
18 but in that particular year it was covered with eider
19 ducks, there were 10,000 to 15,000 birds jammed in
20 one small piece of open water. Now, let's assume that
21 an oil spill had occurred on the ice, and it would look
22 to an eider duck, just like open water, the only open
23 water for hundreds of miles. You can be sure that
24 because the offshore drilling locations are practically
25 on the fringes of the migration route, that literally
26 thousands of birds would come into that "open water"
27 as a spot to feed and rest. This is an exceptionally
28 sensitive area. It would affect not only the eider
29 ducks, but also old squaws, loons, and quite a few
30 other species.

Percy, Grainger, Barry,
Sergeant, Smith, Stein
In Chief

The critical period for eiders ^{when the} males first arrive would be from about the 25th of April until the end of the migration to the eastward, which terminates around the latter part of June. But in the case of the eider duck, that's not the end of it. The male eiders, just as soon as the female has started nesting, migrate back west again to the northern Chukchi Sea, and by early July, that migration is well under way, and is a continual migration back westward for their annual moult. Throughout the season there is continual migration of eiders, either east or west, right up until freezeup. In fact, we've seen eider ducks flying past Johnson Point on Banks Island as late as the 25th of October, even though it was twenty below zero. There was enough open water for them to find places to stop.

Eider ducks feed primarily on the bottom of the ocean. They dive to a considerable depth, and is probably why the shallower open water found off Cape Dalhousie is one of the main concentration points for eiders. We are not very sure of their food habits at this time, although they are known to take clams and probably marine isopods, and other things of that sort. What an undersea contamination might do to the food chain of this particular species, we are not aware of at this time. Other speakers have mentioned some of the bottom problems.

Another area and species to consider as a typical sea bird, namely the murres. The murres nest on cliffs in very large colonies. In the Beaufort Sea area, there is only one colony of murres

Percy, Grainger, Barry,
Sergeant, Smith, Stein
In Chief

and it is relatively small. It is located at the very tip of Cape Parry, near the Parry DFW Line site. It happens to be a migratory bird sanctuary, at the time. It is a small cliff with the necessary combination of an early opening in the water in the areas around the bottom of the cliff. The murre is entirely a marine feeder and the colony at Cape Parry is unique in that there is no other murre colonies for a thousand miles to the east, north of Summerset Island; or to the westward, the nearest murre colony is approximately 1,500 miles away in the north end of the Bering Sea. We have a unique group of birds that are completely controlled by the sea. They feed on the open waters. In fact, we're not even sure their taxonomy is; we assume they are related to the Pacific birds rather than to the Atlantic birds. Their food habits are largely unknown although murrens normally feed on small capelin and other small marine fishes. The murrens also use the ice leads stopping points in their migration, and of course need the open water near the base of the nesting cliffs.

There is in the literature, considerable amount of studies reported on the cleanup of seabirds, once they have become oiled. Oil matts the feathers of the birds and destroys the down insulation, and it also destroys their buoyancy. You'll notice in that picture that the ducks that are in that puddle of oil, are very low in the water. The bird is immediately subjected to the cold waters, and dies of hypothermia. It is possible to remove oil with

Percy, Grainger, Barry,
Sergeant, Smith, Stein
In Chief

1 detergents, but in every case, although the bird may
2 survive briefly after it has been cleaned up, they
3 invariably die. Even in warmer climates, such as at
4 the Santa Barbara oilspill in California, attempts to
5 clean birds and rehabilitate them turned out to be
6 unsuccessful. Some birds were returned to the water,
7 but a close follow-up found that virtually all of them
8 died within a week or two after they had gone through
9 the cleaning process.

10 In the Arctic, with its difficult
11 logistics and perhaps bad ice conditions, when one
12 would expect to have trouble with oil spills, I am
13 extremely pessimistic about any attempts to salvage
14 or rehabilitate any bird that got into an oil spill. With
15 the continual turnover of birds in the migration period,
16 one could expect very high mortalities, as long
17 as the spill lasts. How quickly a spill could be
18 cleaned up is something that I do not know; and I don't
19 think the proponents have been able to come up with
20 a satisfactory answer on how quickly oil could be
21 cleaned up or disbursed.

22 Along the coastal lagoons of
23 the shores of Beaufort Sea, a group of waterfowl,
24 scoters, they're locally called black ducks; scaup
25 and old squaws gather to moult. They arrive in the
26 coastal lagoons in the middle of July, the males come
27 to these areas from inland nesting grounds. They are
28 joined by old squaw ducks, both breeders and non-
29 breeders; primarily male birds and younger females that
30 don't nest until they are two years old. They are

Percy, Grainger, Barry,
Sergeant, Smith, Stein
In Chief

1 flightless for a period from the 15th of July until almost
2 the end of August. Around the Tuk Peninsula approximately
3 600,000 of these ducks are flightless along the various
4 lagoons and barrier beaches. The Tuk Peninsula is not
5 used for moulting in every year. In some years there are
6 very large numbers occurring in Northern Alaska. They
7 are completely helpless during this flightless period.
8 Their only means of escape is to dive and swim from
9 one spot to another. They feed on the various marine
10 fishes and marine invertebrates that are found in the
11 protection of the barrier beaches and the lagoons. Any
12 oil spill that has washed ashore or over the barrier
13 beaches and into the lagoons, would cause very serious
14 damage to this particular population of waterfowl.

15 In the plans for offshore
16 drilling, the two sites that Dome Petroleum has in mind,
17 at the outset, are located near the edge of the shear
18 zone. By the shear zone, that's the boundary between
19 the land-fast ice and the drifting pack ice. This is
20 on the migration route. The logistics of getting to
21 an oil spill when there is moving ice, and how they
22 will drill a relief hole if there were a blowout, are
23 all contained in the scenarios of what would happen
24 should a blowout occur. I understand, these will be
25 presented at this Inquiry by other people who are more
26 familiar with the ice movements and the currents along
27 the coast. Needless to say, one can expect birds to
28 be found any place with open water during the period
29 from the first of May approximately until the end of
30 October. I am not too encouraged by the so-called

11433
Percy, Grainger, Barry,
Sergeant, Smith, Stein
In Chief

1 contingency plans. I had opportunity to see the Dome
2 Petroleum ones. How could they possibly prevent oil
3 from occurring in many areas as the currents move along
4 the coast of the Beaufort Sea? I will not try to
5 reconstruct the scenario of an oil spill. I understand
6 Mr. Millen, Dr. Millen is going to be doing that. In any
7 event, it makes rather grim reading. I am sure it will
8 be presented at this Inquiry another time. The only
9 thing that probably can be done is to pinpoint the
10 place and time where most birds can be expected to
11 occur and thus try to avoid drilling and construction
12 activities at these times and places.

13 It is a difficult thing to do
14 because no two years are the same. 1974, the year of
15 the so-called Beaufort Sea Studies, was one of the
16 poorest ice years on record. The only two years I know
17 of from my experience that were worse was the year 1959,
18 and the year 1964. A year like 1973, which was a very
19 light-ice year, would create a whole different
20 distribution pattern of water fowl, and a whole different
21 set of logistical problems for the drillers and the
22 construction people. I find it difficult to try to
23 predict an impact of something that we have little control
24 over, namely, the weather and the ice. The whole
25 question of environmental impact and environmental
26 impact assessment, and environmental monitoring, disturbs
27 me considerably. I find it difficult to see how an
28 unknown situation can be predicted. An environmental
29 impact is what people are trying to predict might happen
30 in the future, and hence devise ways to alleviate it.

Percy, Grainger, Barry
Sergeant, Smith, Stein
In Chief

I think to monitor an environmental problem is not going to really cure anything. It is just documenting for historical purposes what has actually happened , and after the fact. It is, in the area of the Beaufort Sea, to me, it is complete speculation of what might happen and how things might occur.

The knowledge of wave action and ice action has been determined on the basis of very limited years of experience and I think it would be extremely difficult to make any prediction as to what might occur, and from there to try to predict an impact of what would result. If there is a time when there are big waves, that's storm tides and things like that, and there happens to be a blowout, which direction would the oil spread? There are guesses at some of the -- in some of the oil spill scenarios. To me an impact statement should be related to some historical events, if possible. There are many historical events to which analogies can be drawn, at least on the land operation part of the pipeline. I shall now consider the cross-Delta route and the route along the North Slope , on which I think some remarks should be made, although briefly, at this time.

As I mentioned before, the low flat islands of the Mackenzie Delta, are subjected to storm tides and possible deposition of oil or any other contaminants over large areas, which in turn would probably affect the plant life of the Delta. The Delta is important for snow geese nesting in the

Percy, Grainger, Barry
Sergeant, Smith, Stein
In Chief

1 Kendall Island Bird Sanctuary. It is also an important
2 area for whistling swans; probably one of the most
3 dense nesting areas in North America. There are parts
4 of the Delta which are extremely important to white-
5 fronted geese, many varieties of ducks, such as pintails,
6 mallards, scaup ducks, old squaws, and so forth. There
7 are also sandhill cranes and shore birds nesting in the
8 Delta. The Mackenzie Delta lowlands, and I include
9 the area from Richards Island to Blow River, as an
10 important fall staging area, for geese coming into the
11 Delta. It is one of their first stopping points
12 before they disburse along the coast and the North
13 Slope. It is one of the last places that receives
14 snow cover in the fall. It is a point of departure
15 southward in the fall for many of these birds. In a
16 good year, after Banks Island or Anderson River, or
17 Kendall Island, has had high reproduction; all the
18 snow geese arrive into the Mackenzie Delta's outer
19 islands, with many young with them. Their population
20 could jump as high as 400 to 500,000 birds. The
21 impact of the pipeline through the outer delta's prime
22 nesting and staging area is going to be difficult.

23 There are some historical
24 impacts --

25 THE COMMISSIONER: Maybe we
26 could stop for coffee now. I've found your presentation
27 helpful, but it's densely packed and maybe we could
28 stop for a few minutes, and then we could resume.

29 (PROCEEDINGS ADJOURNED AT 3 P.M.)
30

Percy, Grainger, Barry
Sergeant, Smith, Stein
In Chief

(PROCEEDINGS RESUMED PURSUANT TO ADJOURNMENT)

THE COMMISSIONER: We'll come
to order again.

MR GOUDGE: I suggested to
Mr. Bayly, Mr. Commissioner that in the interest of
continuity it would help me at least if we backed Dr.
Barry up to where he began talking about the cross
Delta which ^{was} I think just a paragraph or so before we
broke.

THE COMMISSIONER: The middle
of page 14. Maybe you'd start again the middle of page
14, Dr. Barry , to preserve our continuity
of thought about the North Slope and the cross Delta.

WITNESS BARRY: The middle of
page 14 or page -- A lot of philosophizing about
environmental impacts and I -- trying to develop the
pure speculation that seems to, in my mind has involved
with the some of the work in the Beaufort Sea where
we're trying to predict ice and weather and their
effects and as far as in the Delta is concerned it's
possible to take advantage of some of the historical
impacts that we can-- so we can draw analogies from
that , and I've -- up through to the middle of page is
we developed that there can be up to 500,000 snow geese
appearing in the Delta at the outer part of the
Mackenzie Delta . There are some historical impacts
that we should try-- from which we should try to draw
analogies. I think it's probably safer to do than to
speculate on what might happen as in the Beaufort Sea

Percy, Grainger, Barry
Sergeant, Smith, Stein
In Chief

1 problem itself. Proponents state that pumping stations
2 along the pipeline route will be spaced fifty miles
3 apart with an airstrip at each one. Some years ago,
4 beginning around 1955, the Distant Early Warning or
5 Dew Line sites were constructed coincidentally every
6 fifty mile along the coast, and built at a time when
7 there was little or no concern for environmental
8 damage. The Dew Line sites were built with tremendous
9 aircraft, land and sea support. The construction of the
10 Dew Line sites involved aircraft in numbers larger than
11 the famous Berlin Airlift. There's a lot of similarity
12 between Dew Line sites and what the proponents say a
13 pumping station will be. I can not for the life of me
14 figure out why they have not done historical studies on
15 what impact the Dew Line sites had on the flora and
16 fauna along the route. Furthermore I find it quite
17 difficult to understand why the Dew Line sites are not
18 themselves used. Why not a site that has already dis-
19 turbed the countryside? The way the route is planned,
20 at least along the North Slope, which is also a very
21 critical area, as brought out in the hearings in Yellow-
22 knife; it is doubling the amount of disturbance of
23 the environment, at least as far as the pumping stations
24 are concerned. The proponents should demonstrate why
25 existing Dew Line sites could not also be used. Dew
26 Line sites are recognized to be obsolete, so why shouldn't
27 the line be constructed to connect between the various
28 sites and make use of them. In crossing the delta the
29 proponents have chosen some of the prime and best water-
30 fowl habitats. The proposed line crosses Moose Channel

Percy, Grainger, Barry
Sergeant, Smith, Stein
In Chief.

1 Flats and in the area of Coal Mine Lake and Moose
2 Channel itself, and crosses Shallow Bay to Ellice
3 Island area which is one of the most concentrated
4 areas for staging geese and also very important for
5 nesting swans, cranes and ducks. In the middle of that
6 area another compressor station is planned. I cannot see
7 why they don't put a compressor station back on the
8 mainland near Shingle Point, where there is already a
9 Dew Line station. Tununik, which is the next Dew Line
10 station to the east is approximately fifty miles from
11 Shingle Point. Why do they have to end up with a
12 compressor station in the middle of the Delta, and with
13 some of the most sensitive areas I know of ?

14 Some years ago I participated in a study that was
15 done for the Arctic Petroleum Producers' Association
16 and financed, at least in part by Imperial Oil, and the
17 Government of Canada or the Canadian Wildlife Service,
18 on the effects of oilwell drilling on wildlife. This
19 was done at the original Taglu discovery site located
20 at the boundary of the Kendall Island Bird Sanctuary. In
21 that study we found noise levels of over 100 decibals.
22 There were frequent helicopter arrival and departures,
23 although I must stress that Imperial Oil followed a
24 prescribed helicopter route to and from the site, be-
25 cause of its environmental sensitivity. The site
26 appeared to have as much activity around it as a
27 compressor station in its construction and operational
28 phase. We had plots for studying nesting densities of
29 birds around that site. Plots were in a 1 ½ mile
30 radius around Taglu. We had a control area

Peloy, George, Barry
 Sergeant, Smith, Stein
 In Chief

behind some hills over by Swan Channel and Richards Island, which was of similar terrain. We found that as far as nesting birds were concerned, approximately 50 percent of them were disturbed enough to have moved out of the area. There were another 30% that seemed to be undisturbed. Then there were some that had nested in traditional nesting sites, for instance swans and geese do that, and they had been nesting there for many generations before the drill rigs suddenly appeared in the spring when they got back from their migrations in the winter. One such swan nest was a quarter of a mile from the rig, but as soon as the young had hatched they took the young considerable distance from the area. In other words they were some of the traditional nest site but as soon as they became mobile again with the young they moved out of the area. Coincidentally I had worked in that area for about three or four seasons before the Taglu drill rig was put in, so we had some background information on the movements of the flightless geese and their broods. The most seriously affected were the whitefronted geese, which evacuated an area for up to ten miles away. The snow geese stayed farther out on the periphery of the outer edge of the Mackenzie Delta and the swans did not use the channels where we had found them with their broods in prior years. The general impact on the area is of course variable depending on each species. Some species were actually attracted to the site. The drilling mud stacked up in pallets provided nesting cover for snow buntings which had not been found nesting in that part of the Delta

Percy, Grainger, Barry
Sergeant, Smith, Stein
In Chief

1 at all. The rig site actually attracted ravens also,
2 in other words there was a plus two of being attracted
3 to this site, even though the company did keep a fairly
4 clean camp and incinerated all their garbage. From
5 studies done by consulting firms and by ourselves at
6 Anderson River and Kendall Island Bird Sanctuaries,
7 has shown that geese, especially flying geese as opposed
8 to molting geese will move and are disturbed by noise
9 of equipment and by helicopter and aircraft. At
10 varying times during the year some will disburse at a
11 distance of up to five or so miles from head of the
12 source of the disturbance, in this case helicopter or
13 compressor station or what have you. I think we can
14 relate what happened at Taglu to what could happen at
15 a compressor station located on the north side of
16 Shallow Bay. I think we can draw firm conclusions on
17 the basis of the historical record of what had happened
18 before. I suggest that an area of five to ten miles
19 depending on how well the aircraft are controlled
20 around the compressor site, will not be used by any
21 staging geese. As I mentioned before anywhere from
22 200 to 500,000 geese, especially snow geese can be found
23 in that area during the latter part of August and
24 through the month of September and in some years in-
25 to October.

26 The construction and operation of the Taglu gas
27 processing plant, is located close to the Taglu
28 wellsite which we have already studied, in fact it's
29 only a few hundred yards away. I can assume, without
30 having all the information as to the size and noise

Percy, Grainger, Barry
Sergeant, Smith, Stein
In Chief

level of the gas plant that it will probably have an impact somewhat similiar to the Taglu drill site. In other words it will have an effect on some species within a five mile radius of the plant site. It will affect the movements of other species in that area, in an area that has already been disturbed. In spite of the fact that it's an already disturbed area I do question why a gas plant , both the one at Taglu and I guess there's one being planned by Shell Oil, cannot be located in less sensitive areas, such as at Tununik on Richards Island.

MR BAYLY: Thank you Dr. Barry.

Mr. Commissioner we just have this machine to finish setting up and perhaps we should do that before we go on .

THE COMMISSIONER: Mr Carter, would you make sure that when the Arctic Gas witnesses relating to the cross-Delta route are brought forward as I think it is intended next week beginning Monday-- make sure that the appropriate witness deals with the question of the sighting of the compressor station in the middle of the delta, in light of Dr. Barry's comment. If you have a witness who can comment on sighting of the Taglu Gas Plant and the Niglintgak Gas Plant you might bring that witness forward as well. I'm not suggesting that you are in a position to do so, but you might consider that and would you also make sure that Dr. Gun reviews Dr. Barry's evidence and comments on his testimony regarding the cross-Delta route and the issues that he's raised there.

Percy, Grainger, Barry
Sergeant, Smith, Stein
In Chief

MR. CARTER: Unfortunately Sir
we just got the evidence last night but I'll do my best.

THE COMMISSIONER: Well, I am
sure that you can get Dr. Barry's evidence to Dr. Gun
before Dr. Gun gets here. I've no doubt of that.

WITNESS BARRY: I might add
that Dr. Gun and I have discussed this in some length,
privately.

THE COMMISSIONER: I am sure
you have, but I'd like to be privy to the discussion
Well, we'll take a moment and you can set this thing up.
Is that what you said ?

MR. BAYLY: Yes, Mr. Commissioner,
and we'll be making these photographs, exhibits or
copies of exhibits before the Inquiry.

THE COMMISSIONER: Fine
Are you ready Mr. Bayly ?

MR. BAYLY: Yes sir . Dr.
Sergeant could you give your evidence to the Inquiry
please ?

WITNESS SERGEANT: The
following 40 slides are an attempt to give a visual
image for approximately the first 8 pages, pages 2 to
9 of my testimony. However -- and also to give some
extrabackground. It will unfortunately be necessary to
go over parts of the testimony again, since I was unable
totally to match the slides to the testimony. The
animals I am going to talk about are two in number and
one is a whalebone whale here; the bowhead as it was
known in the Pacific, and the greenland whale in the

Percy, Grainger, Barry
Sergeant, Smith, Stein
In Chief

1 North Atlantic, reaching about 55 feet. This drawing
2 was made in the North Atlantic in the mid 19th century
3 and the next is a photograph taken by my assistant off
4 Cape Smoking Hills, Baillie Islands area, and you can see
5 why it's gained the name bowhead; the protuberance on
6 the head followed by a hollow and then the back. This
7 is the only Arctic, truly Arctic whalebone whale and as
8 with other Arctic whales it has no back fin. Clearly
9 if we're going to buck ice you don't want a fin which
10 is a fairly soft structure in the way. Occasionally a
11 dead animal may be found on the Tuk Peninsula. We don't
12 know why these animals die, whether these are natural
13 causes or whether these are wounded animals from the
14 nearest hunting which occurs at Point Barrow. We tried
15 to discover with a metal detector on two of these animals
16 but we were not able to establish any good evidence.
17 This animal is one of the most important animals in the
18 whole history of the Inuit, since the Inuit culture
19 spread from North Alaska to Greenland in what is known
20 as the Thule period in about-- I'm not an anthropologist
21 -- but I think about 1000 A.D. is correct.
22 Following this whale is the mainstay of the economy.
23 It was a marine culture and this same culture can still
24 be found at Point Barrow, and even better at, I think
25 at Point Hope, and a few other
26 settlements in North Alaska. The Thule people relied
27 on this whale almost throughout their range except
28 around Victoria Island where they hunted caribou more,
29 and you can find the old Thule houses all over the
30 north particularly in the Eastern Arctic, with still

Percy, Grainger, Barry
Sergeant, Smith, Stein
In Chief

the bones of these animals inside the stone circles. The ribs were used presumably for skin tents above the stone circles and these are mostly the bones that are being used for carving at the present time. Apparently these bones need to be dry, free of oil before they're carved and I'm told that this leeching of the oil takes a long time.

The animal also became very important for European and North American hunting later starting from the other side, from the North Atlantic. This was first for oil with the Dutch in Spitzbergen, who then pretty well extirpated the animal, then the other Europeans joined in; the British and the Scots and others, around Greenland, finally into Davis Strait and Baffin Bay and later on in the fishery the baleen or whale bone became very important as corset stays, riding whips, and other material, for other things like that. And that is showing the six foot baleen, of the larger of the two animals we found in the Tuk Peninsula, and the smaller animal on the right, which stranded themselves for unknown causes. That's Mr. Hoek who has worked on this project with me.

The animal was almost extirpated from the North Atlantic and is now coming back in the Canadian Eastern Arctic Archipelago fairly satisfactorily. We see-- we saw about 15 last summer while working on narwhals. In the North Pacific it was fished later mainly from New England and then from San Francisco and Hawaii by the American whalers and from the 1860's onwards, and they came round finally to Herschel Island at the

Percy, Grainger, Barry
Sergeant, Smith, Stein
In Chief

1 end of the fishery and wintered there and this is
2 when the major white contact with the people on this
3 coast occurred. It was a fairly disastrous contact
4 in that most of the original inhabitants of the delta
5 who apparently , about two to four thousand in number
6 died from diseases obtained from their first contact
7 with large numbers of white people, measles, diptheria
8 and the usual infectious diseases, and most of the
9 people who live here I understand now, came at various
10 times from Alaska, although there is some-- a few
11 original inhabitants survived and apparently the
12 whaling culture in the delta survived-- more or less intact
13 of hunting, which was by kayaks , but the processing
14 of the small whales, the white whales.

15 This shows the-- where the
16 bowhead in the Beaufort Sea-- how it came into this
17 part of the world, from the logs of one whaling ship
18 which hunted fairly extensively. The animals winter
19 in the Bering Sea and down to the Okhotsk Sea on the
20 Russian side, come in through the Bering Strait in
21 early summer, move apparently to some degree northward
22 but to quite a considerable degree along the North
23 Alaskan coast following the shore lead and several
24 recent expeditions have shown how they come along this
25 wide shore lead or set of shore leads in early May,
26 in April and May when they are hunted from Point Hope
27 and Barrow and other places. The animals or some
28 of them finally come into this sector of the Beaufort
29 Sea in summer and may penetrate as far as the strait
30 between Banks and Victoria Islands-- in an open summer

Percy, Grainger, Barry
Sergeant, Smith, Stein
In Chief

They then move out again in September. That row of black dots-- they're dots, squares are in September, and they're moving out again quite rapidly in the first half of September.

This year in '75 was a rather intriguing year as everybody knows; the supply fleet for Prudhoe had great trouble at the end of August and early September, and this recalls an episode when the American whaling fleet was badly stuck at about that same time of year in about 1870-- I forget the exact date-- and they had to leave the whole fleet and get away on boats and join the few ships that hadn't gone so far. This occurred at Wainwright and the whole ships were lost but no people were lost.

The whales also this year appear to have had some trouble getting out from the delta region in the fall, but they seem to manage to slip out along the coast. The Americans were doing a survey after we left off -- after, in distance I mean. In the spring these animals seem to move in along the main leads, in May and they live on the plankton -- probably the larger planktonic small shrimps, although the food of this animal is rather poorly done because it has not been caught by white man in the modern whaling period, and in the 19th century there were not too many precise observations. But it strains the small animals of the sea with its whalebone or baleen and it can strain very small animals. That is why it has this very fine baleen.

Our modern observations

The other species that occurs

here is the white whale or beluga-- the second name really means white animal-- it's a Russian name but it's usually applied to a sturgeon, and belukha is the Russian version of the whale, so I prefer to use white whale. This is taken at Churchill. I'm sorry it's

Percy, Grainger, Barry
~~Sergeant~~, Smith, Stein
In Chief

1 a dirty slide, and there was at one time a fishery.
2 at Churchill on the Churchill River estuary in Manitoba
3 and I was able to study this animal there. The head of
4 a white whale. This is a toothed whale or porpoise. It
5 has a small eye and an even smaller ear, which I think
6 may be visible behind. It starts life as a small ^{brown} calf,
7 becomes grey and finally becomes white, in adulthood,
8 and it has about ten, eleven teeth in each jaw on each
9 side. It doesn't use them for chewing but it does make
10 jaw clapping noises apparently and it takes its food
11 mostly by suction as many sea mammals do . It is like
12 most of the porpoises, a highly social animal. A small
13 population lives all the year in the Saguenay and
14 St. Lawrence region where the water is very cold, all the
15 year, and it's most easily seen there in Southern Canada,
16 and one sees this behaviour which has recently been
17 explained to me by a young graduate student. The animals
18 are herding fish by this line behaviour, and sometimes
19 the animals, besides coming around and letting others
20 get the fish-- quite high level group activity. Another
21 place where we have studied these animals is in an inlet
22 in northern Somerset Island called Cunningham Inlet .
23 This concentration was first noted by Tom Barry in the
24 late '70's -- late '50's but it wasn't until 1973, when
25 with the Eastern Arctic Pipeline becoming important as
26 a concept, that we decided to have a thorough look at this
27 and it turned out to be a very interesting place to
28 study them because they were, first of all very closely
29 accessible, secondly the water was relatively clear; we
30 could see more or less what they were doing, which was

Percy, Grainger, Barry
Sergeant, Smith, Stein
In Chief

1 not true in the Mackenzie. The group usually numbers
2 over a thousand in a small river estuary running off
3 a limestone lowlands. This is Dr. Doug Hayland of Quebec
4 City who is quite interested in remote sensing of these
5 animals and I've been consulting him on some of the
6 techniques. He has actually surveyed this group with
7 aerial survey photography and estimated the size dis-
8 tribution and so on, by that method. Seen from the air
9 a mass of animals in the period late July, first half
10 of August in the river mouth and only in that period.
11 They cannot get there earlier because of the ice in the
12 inlet and they leave it again. And this is a very wide-
13 spread phenomenon in the Arctic. Now the significance
14 of this was not determined until fairly recently. Most
15 people thought the animals were feeding. The animal
16 occurs throughout the Arctic and lower Arctic also, in-
17 cluding all the Siberian Coast which is really a mass of
18 rivers and estuaries, almost joining up and most of the
19 work is being done by the Russians. But when we found
20 these animals in a cold-- really cold polar sea, we could
21 see that the rivers had the significance of warm water
22 in summer. The delta, as I pointed out. It was very
23 difficult to see what was going on, and it still is
24 because of the coffee coloured water and most of our
25 observations are made elsewhere and we infer in the
26 delta what is happening underneath that silt. The animals
27 just-- their backs break the surface and we can count
28 them but we can't see the calves which are brown and we
29 can't see the grey animals very well.

30 Well, there the animals on the

Their movements in the Beaufort

the period when these animals come in is when the net melting of the leads in the daytime exceeds the freezing at night. And at night the beluga, white whales apparently sleep at the surface of the lead and it freezes and they leave an impression of their nose, and you can see these 20 or 30 little impressions in the ice from the air, and then they move on again. But if they came in earlier than that there would be a net freezing of the leads, so that timing of the migration is critical.

They then come in the month of June into the whole Beaufort Sea as far as we can see and we infer that they're feeding in the leads probably on the polar cod. One of the people who saw them there was Stephansson who crossed over from somewhere in Alaska to Banks, and observed this in late May, with these white whales in the lead as he was sledging across and he described the plankton bloom and this very rich developement of plankton that Dr. Grainger mentioned. They don't-- in late June they can still be seen-- apparently in 1974, a rather cold year pressing on the eastern end of the range trying to get as far as they could. Perhaps they use up the polar cod as they go and-- because there are a large number of them and always

Percy, Grainger, Barry
Sergeant, Smith, Stein
In Chief

1 searching for fresh fields and pastures. But
2 then in July they move into the delta and this I think
3 was '74, and you can see a large percentage of the
4 sightings then come towards the delta or into the delta.
5 And the second half of July-- not quite so marked but
6 still the same distribution. Then in August when sightings
7 are rather few, I think because in open water the wave
8 action makes sightings more difficult, they are spread
9 out at sea again, and there is actually a movement into
10 the Liverpool Bay area; not shown very well there, late
11 July and August, possibly in connection with the number
12 of sea herring in that area but this is speculation or
13 inference, small bits of evidence, Then as with the
14 bowheads they move out west again in early September and
15 go into the Bering Sea as far as we know in winter.

16 We have been able to esti-
17 mate numbers by finding the maximum concentrations in
18 the delta in summer. This probably does not include all
19 the animals. The first observations we made in 1961,
20 1969 showed rather low numbers. I don't know whether this
21 was due to inexperience and first case too late a date,
22 or whether it was real. But any rate it then appeared
23 that we were getting increased numbers up to 1974 when
24 we had the biggest numbers of all, somewhere around 5,000
25 in the delta, and then they fell off again somewhat
26 in 1975.

27 To anticipate it looks as if
28 the delta is a calving sight-- c-a-l-v-i-n-g -- and
29 what happened in 1974, was since it was a very cold year
30 they needed to come to the very warm water for calving,

Percy, Grainger, Barry
Sergeant, Smith, Stein
In Chief

1 they came further in than usual, and therefore concen-
2 trated more and more easier to count than if they were
3 dispersed. We then got an approach towards a real total
4 or the highest total we could get, of about 5000 animals
5 plus more in the Beaufort Sea. So the animal-- the
6 population in this area numbers at least 5000. There are
7 no other rivers that we know of where animals concent-
8 rate regularly other than halfway along the North Alaska
9 Coast and once in the 1950's in Northern Banks, two
10 small rivers there which are probably not open to them
11 in hard climatic years.

12 The other thing that that map
13 shows is, for my own data which wasn't complete, the
14 increase in the number of artifical islands and a
15 proposal I shall be mentioning later for an area where
16 a sanctuary might be created free of human disturbance.

17 Well, the distribution of these
18 animals in the delta as shown by the very excellent
19 studies of Slaney, over four years is shown here by
20 figures that I lifted from the most recent report which
21 reached me about two weeks ago, and it's fairly clear
22 that in 1975 at least, the biggest concentration of
23 animals was in this western Mackenzie Bay region. A
24 smaller one in Kugmallit Bay near Tuk and also a smaller
25 one in the central Mackenzie Bay region, and only
26 transient animals in ^{the} Pullen Island area. This appears
27 to be a fairly typical pattern. Slaney have here grouped
28 three years data, which makes it a little confusing but
29 it does appear that the general pattern doesn't change
30 very much; that there are something like three main

Percy, Grainger, Barry
Sergeant, Smith, Stein
In Chief

1 groups and a smaller transient group. Now if you
2 look at these in relation to the river flow, these are
3 equivalent in size to the-- in a general way to the
4 flow of water in the various channels in the Mackenzie,
5 The warm water in July. I haven't got the accurate cubic
6 feet per second data, but there are three major channels,
7 the east channel, the two west branches and a rather
8 small outlet near Kendall Island.

9 Now, Dr. Grainger did a temperature
10 survey on a cruise of the "North Star" in 1973,
11 and my extrapolation of his temperature data shows that
12 the warmest water is indeed at those two biggest concentrations
13 of the western channels where the highest
14 temperatures occurred up to 17 degrees celsius, and in
15 Kugmallit Bay with rather lower temperatures, around
16 11 at Kendall Island. So the easiest explanation of the
17 disposition of whales at this period is that they're
18 seeking the warmest water.

19 THE COMMISSIONER: Dr. Sergeant
20 there was some discussion earlier on, I think by Dr.
21 Bliss about whether any whales, any white whales could
22 be found in the summer in Liverpool Bay. Do you have
23 any comment on that, are any of them to be found there?

24 WITNESS SERGEANT: Yes, we've
25 had people working there for a long time, Dr. Grainger's
26 staff. We don't think they calve there but we think they--
27 I think the Slaney Report showed quite well that they
28 move there rather late in July, apparently after the
29 calving season, and it's a feeding area. We don't think
30 there's any calving areas of any significance. It's

Percy, Grainger, Barry
Sergeant, Smith, Stein
In Chief

1 colder water. They don't seem to come into the Anderson
2 River mouth. Perhaps it doesn't open early enough, or
3 something.

4 The animal has been of interest
5 to man for some time, and the -- I'll mention the com-
6 mercial fishery that existed at Churchill until the
7 early 60's . It really disappeared when the factory got
8 decrepit. The meat was used for mink ranches in Sask-
9 atchewan, and Manitoba, and the Cree, Chipewyan and Inuit
10 hunters at Churchill were paid by the foot so they carved
11 their initials in whale to show the claimant, and you
12 can see a grey calf and yearling animal and some white
13 adults.

14 In the delta the 19th century
15 history of whaling is very interesting, and it appears
16 that a large number of kayaks drove whales into the
17 east channel. It took about 200 kayaks and it seemed to
18 have been one big hunt. In this century it's been hunt-
19 ing animals singly or-- and at present this is done
20 by powered canoes. But the use of the muktuk, which is
21 the outer layer of the fat, and of the meat which is
22 dried in the sun, has seemed to have remained the same,
23 and this is still quite an important dietary supplement,
24 and the hunters of course-- very much of a
25 recreational event. And here at Kendall some years ago,
26 some of the heads and flippers which we usually put in
27 permafrost pits I recollect, and the meat drying, and I
28 forget the exact treatment of the muktuk but it was
29 rightly boiled I think and then dried.

30 In the Eastern Arctic, this is

Percy, Grainger, Barry
Sergeant, Smith, Stein
In Chief

1 at Whale Cove, The muktuk was eaten
2 frozen. I think it's probably better to do that because
3 it has a high vitamin C content which would be killed
4 by boiling; at any rate, it's quite an important dietary
5 to supplement. I think particularly in late winter it
6 has, if I recollect, and I'm not a bio-chemist, quite
7 high contents of vitamin A and D also.

8 Now this matter of the river
9 mouth, Cunningham Inlet again from the air, it can be
10 clearly seen there that there are many young calves
11 -- there is one sitting on the mother's back and another
12 one, I think, on the right middle suckling. We earlier
13 discovered from a similar site in Hudsons Bay that there
14 were young calves and we deduced that these rivers
15 are entered for purposes of calving. There is very
16 little in the stomachs of the animals in such situa-
17 tions. The feature of this animal, the calf is born
18 without a blubber layer, so it is not insulated.
19 The animals apparently remain in this warm water
20 for a few days or possibly weeks, and then go to sea
21 again when the calf has the blubber layer.

22 It appears that the narwhal
23 doesn't use this strategy, it lives in deep cold
24 water all the time, and the calf is born with quite
25 a thick layer of fat. The bowhead is probably big
26 enough that it doesn't matter, the cold water doesn't
27 matter to it.

28 However, this in the delta
29 is inference for the most part, although sporadic
30 sighting of the calves were certainly described by

Percy, Grainger, Barry,
~~Sergeant~~, Smith, Stein
 In Chief

1 Slaney in both Kugmallit Bay and in western Mackenzie
 2 Bay. The rest of the pictures merely shown some of the
 3 activity in the delta. This is hunting by canoe as
 4 occurs mainly, I understand now, in Kugmallit Bay, formerly
 5 also at Kendall and Tent Islands, such-like sites. This
 6 is our own research ship the "Salvelinus" which has been
 7 in the delta for about fifteen years and Liverpool Bay
 8 area and has done a lot of work, particularly on
 9 fisheries/ and then this new activity, island building and I
 10 have some notes here that this was Immerk in '73. This
 11 was Immerk and associated structures in '75. This is
 12 Sun Oil Pullen, '74. These were all in July. This is
 13 the same.

14 This is just listed as a rig
 15 Mackenzie Bay, not identified. I don't know if anybody
 16 can. This was Adgo, '75 and this was Pelly Barge, '75;
 17 hope I got that right, yes.

18 Our own researchers in the delta -
 19 I'm starting on page three here at the bottom -- went on
 20 intermittently from 1955 onwards. We earlier discovered
 21 that we couldn't find very much about the biology of
 22 the animals from the catch because the catch was highly
 23 selective of large animals. This is true in other places
 24 too, like Churchill and clearly it shows that the catching
 25 -- if from that standpoint -- conserves the animals.
 26 A certain amount of wastage of course, does not.

27 I mentioned the research done --

28 THE COMMISSIONER: Do you mind
 29 repeating that? The catch consists mainly of large
 30 animals?

Percy, Grainger, Barry,
Sergeant, Smith, Stein
In Chief

1 A In other words, the Inuit
2 select the big animals -- I should expand that. The
3 males are bigger than the females and therefore, this
4 type of catch takes about 70 percent or more males.
5 Therefore, other things being equal, this should conserve
6 the herds because there's probably a surplus of males.
7 However, the wastage rate of present killing is fairly
8 high. It cannot be measured but stranded carcasses
9 are found around the coast, some people say about 50
10 percent losses over and above the catch which is around
11 about 130 animals, a summer.

12 So, although our earlier research
13 was looking at the basic biology of the animals and
14 considering whether the catch was excessive, it would
15 appear, as I gather some earlier testimony by Dr. Bliss
16 also included, that with a population in the excess of
17 5,000 and catch of perhaps 200 thousand, including the
18 deaths; this is quite a conservative catch. Certainly,
19 it has been stable for many years, since at least the
20 1930's. The newer activities are, on the other hand,
21 have clearly increased the human disturbance of the
22 animals in the sense there are more vehicles and noises
23 going on in the delta.

24 I have perused the Slaney
25 reports and I find that really our own studies and the
26 Slaney studies seem to be totally in agreement in any-
27 thing that we have studied in parallel, and clearly the
28 which
Slaney studies/have been more intensive in the delta for
29 the last four ^{years} have marked the distribution in the delta
30 much more thoroughly than we have done.

Polcy, Grainger, Barry,
~~Sergeant~~, Smith, Stein
In Chief

1 I mentioned the concentration
2 of the animals towards the western part of the delta
3 and table one exemplifies this. I divided the delta into
4 three more or less equal sized parts. The western one
5 from Shingle Point to Garry Island, the central from
6 Garry to Pullen and eastern from Pullen to Toker Point,
7 thereby excluding areas east and west of the delta
8 proper. Using our own currents in various years,
9 excluding 1961 which had very low totals, and may not
10 have been complete or may have been too late in the
11 season in a warm year; it appears that in every year,
12 more than 50 percent of the animals and a mean of 60
13 percent occurred in that western sector. This may
14 include one or two groups of whales, the bigger one
15 usually in the southwest sector of this rather vague
16 piece of sea, generally called western Mackenzie Bay,
17 bounded on its upperstream part by Shallow Bay and with
18 a small dent called Shoalwater Bay with the nearest
19 hunting at Tent Island, in some years at least.

20 I've already suggested that the
21 simplest correlation of the distribution of the whales
22 is that the biggest groups are in the warmest water and
23 since we have found in every area we worked that the
24 warm-water concentrations, which in the delta, as else-
25 where are only temporary for the period, roughly, of the
26 month of July. Since these are always in other regions
27 associated with calving then this what is happening in
28 the delta with these groups.

29 There is very little feeding
30 in the delta at all. In fact, as you've probably heard,

Percy, Grainger, Barry,
Sergeant, Smith, Stein
In Chief

1 there is very little food in the delta estuarine
2 waters of a suitable size for a white whale. The river
3 fish would appear to concentrate in the very shallow
4 waters indeed where the whales cannot follow them with-
5 out risk of stranding themselves. The few stomach
6 contents we have, suggest that the animals are feeding
7 at sea before they come in. In other words, all that is
8 left is hard cartilaginous parts, horny beaks of squid.

9 There appear to be no other
10 major rivers utilized. It's rather difficult to say
11 whether any other rivers could be utilized as an alter-
12 native -- the Anderson perhaps, but it's not very big
13 and it maybe breaks up a little later, and perhaps it
14 would hardly take 5,000 animals.

15 I should say that this is the
16 biggest concentration in the river mouth except for the
17 Nelson which is the outlet of the Saskatchewan River
18 into Hudson Bay and this also has about the same order
19 of numbers in summer.

20 Then comes the controversial
21 question of what kind of disturbance is created by
22 human activity to these whales, whether by hunting or
23 by the activities of other boats or other noisy activities
24 associated with the oil and gas industry. Well, the
25 difficulty with whales is you can't really put them in
26 the aquarium. I suppose we could ask Vancouver or New
27 York if we could experiment with their animals but they're
28 rather valuable so that we really have to infer from
29 field observations.

30 We have found at Churchill that

Percy, Grainger, Barry,
Sergeant, Smith, Stein
In Chief

1 white whales can tolerate human noise and activity.
2 For instance, at Churchill Docks, where the mouth of the
3 Churchill River is quite narrow, white whales constantly
4 pass and repass the ships which are loading grain during
5 the summer months. However, there is some evidence that
6 calving concentrations are more sensitive to human dis-
7 turbance. Thus, the number of whales at Churchill is
8 quite small in summer as compared with the Seal River
9 which is a small river about 30 kilometers to the north.
10 Moreover, many of the whales at Churchill are in the
11 mouth of the river and they are feeding on a small fish
12 called capelin, really outside the river mouth and moving
13 in with the tide and out again as the fish do.

14 Yet the Churchill River is much
15 bigger than the Seal River and for many years we wondered
16 what the Seal River concentration of about 1500 animals
17 in the summer was all about so we hired some canoes from
18 the local cooperative; when whaling went out, they were
19 sports hunting and they said "But we can't charter to a
20 government department". We said "we'll pay just as good
21 money as the tourists"; so we chartered ten canoes and
22 we drove them in and we had sort of beginners luck and
23 at low water in the Seal River we found these things had
24 the small calves which was how we discovered what was
25 happening on this river. It was too small to have
26 anything for the animals to feed on.

27 Now, we surmise that the
28 Churchill River was once a good calving area. In fact,
29 in 1950 when Dr. Doan from Winnipeg first went there
30 to study white whales, as a result of their early researches

Percy, Grainger, Barry
Sergeant, Smith, Stein
In Chief

1 they set up the top of the Churchill River estuary as
2 a sanctuary for calving animals but, quite clearly,
3 there were fewer animals there than at the Seal and I
4 really think it's a better area because it's a bigger
5 river. We surmised that the Churchill River, with the
6 settlement, at some point, which we couldn't identify,
7 perhaps a long while back -- perhaps in 1932 -- 1929 - '32
8 when the railway extended to Churchill -- perhaps sub-
9 sequently when the traffic increased and the ouboard
10 came in, the animals moved to the Seal River for a
11 calving site but continue to use the Churchill estuary
12 chiefly as a feeding site. They're only a short distance
13 apart.

14 This does produce some rather
15 circumstantial evidence that perhaps the animals that
16 are calving do require a rather quieter environment than
17 the other animals.

18 At Cunningham Inlet and Lancaster
19 Sound where we have been able to approach these animals
20 very closely on the shore without disturbing them at
21 all, you've only to skip a pebble at the top of the
22 group of animals upstream and they'll panic. Presumably,
23 the predators of white whales are things like killer whales
24 and they're in the water. Polar bears don't often get
25 at them, even in these situations. This Cunningham Inlet
26 group was a calving group.

27 Low flying aircraft do cause
28 disturbance, but airborne sound doesn't disturb to the
29 degree of waterborne sound. None of these statements have
30 been quantified in any way. We haven't started looking

Percy, Grainger, Barry,
Sergeant, Smith, Stein
In Chief

1 at the sound pressures and frequencies which disturb
2 whales in different situations, but quite clearly they're
3 much more sensitive to waterborne than to airborne
4 sounds.

5 Both Slaney and ourselves have
6 looked closely at the correlations of human activity
7 and whale behavior in the delta and I don't think either
8 of us have reached any conclusive statements. Slaney
9 has summarized it very well in their most recent report,
10 if I may quote.

11 "The apparent variability in the reaction of whales
12 to boats may be the result of a number of factors.
13 For example, water depth, nearness of obstacles
14 such as shallow water or land, boat type, boat speed,
15 traffic intensity, recent experience of the whales
16 and whether or not the whales are pregnant or
17 accompanied by a calf. These factors, either
18 singly or in combination could reasonably be
19 expected to result in a change in the response of
20 whales to the presence of a boat."

21 Nevertheless, I would wish ^{to} express my opinion
22 that the calving animals are more sensitive than the
23 other animals from observations. I regret--

24 MR. GOUDGE: I wonder Dr. if
25 you can identify the document you read from?

26 A I'm sorry. Slaney 1975
27 White Whale Study for Imperial Oil Limited, Calgary, page
28 37, "Impact on Whales and Whale Hunting".

29 As far as I can see, the island
30 building activity disturbs the transient groups of whales

Percy, Grainger, Barry,
Sergeant, Smith, Stein
In Chief

1 to a slight degree, rather as Churchill Harbour did
2 and possibly they acclimate to this. I would speculate
3 that the calving groups of whales might be more sensitive.
4 It's difficult for a man to put himself in the position
5 of a calving whale. Possibly, the women in the audience
6 might be able to do so more readily. But I suppose that.

8 Last night, in room 55 in the
9 Mackenzie Hotel, I was above the bar and low frequency
10 sound from the floor through the bar, through the legs
11 of my bed, was quite disturbing and I presume that this
12 would be the effect of a variety of waterborne sounds --
13 propellers, dredges, you name it. Probably it's quite
14 disturbing in a maternity ward, although I can't really
15 go much further than that.

16 There has, in the western part
17 of the delta, where the biggest herds of whales have
18 occurred since '69, inclusive at least, there has to
19 date, been very little human activity. However, there
20 are two proposals, or one activity and two proposals.
21 One is of course, the Canadian Arctic Gas pipeline pro-
22 posal to cross the delta a little bit upstream of the
23 main concentration. The nearest island, as far as I
24 can see from "Oilweek" which is called Ikattok, I believe,
25 a little bit downstream of that southwestern concentration
26 and some activity with Ikattok and Adgo in that
27 secondary western concentration --

28 THE COMMISSIONER: Excuse me,
29 Dr. Sergeant, I wonder if you could just point those
30 areas out on this map? This is not a bad map here and --

Percy, Grainger, Barry,
Sergeant, Smith, Stein
In Chief

1
2 A I am pointing from a map
3 in "Oilweek" of December 8 and it's rather hard to
4 overlay all this because they're all different scales
5 but the pipeline we have a mark -- the position of
6 Ikattok appears to be approximately there, Imperial
7 J-17. I think that's about it. Adgo, I have got two
8 sites, about here and here. One is, a C-15 a P25
9 and F-28, are all labelled Imperial Adgo so I don't know
10 which is which. According to that information those are
11 the nearest islands -- the map does not distinguish
12 actual past potential -- I don't know the symbols used.

13 THE COMMISSIONER: No, that's
14 fine. You said that the crossing was upstream or
15 downstream of the main concentration?

16 A It is upstream. In some
17 the
18 testimony, which I was shown in which/representative of
19 Slaney's was crossquestioned -- Mr. Webb -- I think
20 the implication was that the whales rarely went as far
21 as that but they didn't descend in intervals. There is
22 a slight tidal movement by the animals. There is a
23 very slight tide here, it's probably a slight up and down
24 movement and if I may copy that on the map if I still
25 have it here.

26 The 1975 distribution as shown
27 by Slaney is approximately here. Again, I gather
28 from the early evidence it is somewhat upstream of that.

29 THE COMMISSIONER: Just one thing
30 and Mr. Goudge, you might check the transcript overnight.
My recollection is that Mr. Webb came to this same map

Percy, Grainger, Barry,
Sergeant, Smith, Stein
In Chief

1 and indicated that in one recent year, I think he said
2 that this year, not this year, last year -- one to two
3 thousand animals came in as far as the mouth of Reindeer
4 Channel which is here, upstream actually over the
5 crossing. I am not troubling you with this, Dr. Sergeant,
6 but you might just check the transcript and we'll look
7 at that tomorrow.

8
9 A I checked that transcript
10 and I could not find from his testimony what point he
11 was referring to.

12 THE COMMISSIONER: Well he was
13 at this --

14 A He showed it on the map.
15 THE COMMISSIONER:
16 This is Reindeer Channel
17 and the mouth of Reindeer Channel as you see, is very
18 slightly upstream if not coincident with the crossing.
19 That is what concerned me at the time and that is the
20 only reason I -- but at any rate, all of the offshore
21 islands are certainly downstream of the main concentration
22 across Mackenzie Bay. I've no doubt about that. Good. I've
23 got that right.

24 MR. GOUDGE: What he said
25 sir -- or least a preliminary identification of what
26 Mr. Webb said was that for two years, 1972 and again in
27 1975, they've been seen as far as the mouth of this
28 Channel, which, I believe, is Reindeer Channel, that's
29 still some twenty or thirty miles from the end of
30 Shallow Bay and two of the four years, they haven't been
seen in that far.

Percy, Grainger, Barry,
Sergeant, Smith, Stein
In Chief

MR. CARTER: Sir, Mr. Webb will
be here with the environmental panel for Arctic Gas.

THE COMMISSIONER: Right.

MR. GOUDGE: Perhaps, sir, I
would show this to Dr. Sergeant the end of the day.

THE COMMISSIONER: Show it to
Dr. Sergeant overnight and he can review it.

MR. GOUDGE: Yes, sir.

A At that point, I have
a certain dilemma in that if --

THE COMMISSIONER: Excuse me,
Dr. Sergeant, this is an important question and that's
why I had Mr. Webb go to the map and my recollection --
because I do remember some of things that occur here --
is that he put his hand on the map above -- upstream of
the crossing at the mouth of Reindeer Channel and said
"one to two thousand animals in each of those two years"
and, though they didn't appear in other years, he was
inclined to think, and you might check his evidence on
this, that it was the turbidity of the water which made
sittings difficult at the best of times --

A M-hm. It was very turbid.

THE COMMISSIONER: -- that
may have accounted for the absence of any whales so far
as they could see in those years when they observed none.
At any rate, I just want to make sure that we're getting
your opinion on that very important question and that
you have clear understanding of what he said. When's he--
you said that he was coming next week, is that it?
Next week?

Percy, Grainger, Barry,
Sergeant, Smith, Stein
In Chief

MR. CARTER: Yes sir.

THE COMMISSIONER: Well pick --
now, have you got something else?

MR. GOUDGE: No, sir, but
there's a fairly lengthy passage, perhaps Dr. Sergeant
would like to look at it overnight.

A I have the transcript here.

THE COMMISSIONER: Well, you
don't have to look at it. We'll all be here tomorrow
morning and I see the Bayly^{children} have begun to arrive,
so we may well have to adjourn soon. But, carry on
Dr. Sergeant and we'll return to that in the morning,
perhaps, if you don't mind.

A At this point, I'm in some-
thing of a dilemma, because if it were necessary to
obtain conclusive scientific evidence, it would be
clearly necessary to have some precise quantitative
information on the quantity and kinds of underwater noise
which proved disturbing to whales. On the other hand,
there is the risk that with the gradual approach of
increasing disturbance to that area, with, I suppose
an extension of island building in that general direction,
as shown by the testimony of Mr. Shearer, I gather--

THE COMMISSIONER: Yes.

A The area would be almost
completely invested at least by human activity. It
would seem to me reasonable therefore, that some protective
mechanism should be afforded these animals on the
assumption that development continues. I have proposed

Percy, Grainger, Barry,
Sergeant, Smith, Stein,
In Chief

1 that a sanctuary be created in that region in which there
2 be no human activity.

3 THE COMMISSIONER: Well, Dr.
4 Sergeant, I think this is an important proposal you are
5 about to present and I think we might adjourn now and
6 you could begin again in the morning and though I wouldn't
7 adjourn early except we have hearing tonight at eight
8 o'clock tonight at the Legion to hear the people of the
9 community and certainly all present are invited to attend.
10 But it may be a late evening so I think we'll stop now
11 and start again at 9:30 in the morning, would that be
12 all right?

13 MR. GOUDGE: As far as I'm
14 concerned, yes sir. I wonder is ten o'clock preferable
15 given that there'll have to be some setting up of shop.

16 THE COMMISSIONER: Yes, let's
17 make it ten o'clock.

18 MR. BAYLY: I'm just trying
19 to get through this before Mr. Yates and company arrive.

20 THE COMMISSIONER: Well, I
21 think we'll make it ten o'clock. It's a long day --

22 MR. GOUDGE: There's equipment
23 that has to be set up sir, tomorrow morning.

24 THE COMMISSIONER: It's a long
25 day and a long night, so -- a long evening anyway.
26 Well, ten o'clock in the morning and for those who wish
27 to attend tonight, eight o'clock tonight at the Legion.
